Hopi

K C Hill, University of Arizona, Tucson, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

Hopi is a Uto-Aztecan language of northeastern Arizona spoken by about 5000 people. Hopi culture focuses a rich ceremonial life on arid land corn (maize) cultivation.

Hopi orthography, which has become semi-official since the publication of the *Hopi dictionary* (Hopi Dictionary Project 1998), uses letter values close to those of the International Phonetic Alphabet but with some exceptions. The palatal glide is orthographic *y*. The high back unrounded vowel is orthographic *u*. Various letter combinations, such as *kw, ky, ng, ngw, ngy, qw, ts,* represent unitary sounds. Long vowels are written double. The apostrophe represents the glottal stop and is not written in word-initial position. Word stress is largely predictable, and only exceptional stress is represented orthographically. Unmarked stress is on the first syllable of disyllabic words and on the syllable containing the second mora of longer words, in other words, it is on the first syllable if it is long, i.e., has a long (double) vowel or ends in a consonant, and on the second syllable if the first syllable is short.

Hopi belongs to the Northern group of Uto-Aztecan languages. A diagnostic sound change for Northern Uto-Aztecan (NUA) is the development of Proto-Uto-Aztecan medial affricate *c to NUA -y-, cf. the words for 'moon', Hopi *muuya,* Nahuatl *mētztli*.

Because of the influence of the writings of B. L. Whorf, Hopi achieved a notoriety as a "timeless language" (Carroll, 1956: 216). As a response to this notion, Malotki devoted a large monograph (1983) to the demonstration that Hopi has an extensive way of talking about time and things temporal. Even Whorf's central claim that Hopi lacks spatial metaphors for time (Whorf, 1941: 83) does not hold up. The very word *qeni* 'space, room (for)' can be used with the sense 'time':

(1) Ya pumu-y kiihu-t
Q those-ACC house-ACC
amùu-tsa-ve hìisaq qeni?
them-between-at how.much space
How much space is there between those two houses?

(2) U-ngem qa qeni.
you-for not space
There's no room for you.

(3) Ya ùu-pe qa qeni, um nuy
Q you-at not space, you me
mihikqw tutuqayna-ni-qö?
at.night be.teaching-FUT-SUBORD(switch-reference)
Is there adequate time for you to teach me tonight?

(4) Pas qa qeni; pay kya as
very not space; already POTEN perhaps
ayo'wat santi-t aw qéni-ni.
to.another week-ACC to.it space-FUT
There is no time; maybe next week there will be time.

Nor is counting units of time foreign to Hopi, as seen in the following examples:

(5) Sunat yàasangwu-y sen hóyokpu-t
twenty year-ACC whether increased.amount-ACC
ang pep yes-kyàakyangw
along.it there live-SUBORD
qa hii-ta aw yuku-ya.
not anything-ACC to:it fix-PL
They stayed there twenty years and maybe more, but they never fixed anything.

(6) Pam siiva-y angsakis koyolaw-qw
he [his.own] money-ACC each.time be.stashing. away-SUBOR
oovi naalö-q yàasangwu-y ang
that's.why four-ACC year-ACC along-it
pam aw a'ni àmti.
he to.it very accumulate
Because he kept stashing away his money each time [that he got paid], after four years it really accumulated.

Typologically, Hopi is a head-final, left-branching language; it has a rigid Subject-Object-Verb structure:

(7) Taaqa taavo-t niina.
man rabbit-ACC kill
The man killed a/the rabbit.

and subordinate clauses precede the main clause:

(8) Pam peehu-t sami-t
he some-ACC fresh:corn-ACC
a'ki-qe pu' nima.
pick:corn-SUBORD then go:home
He went home when he had picked some fresh corn.

Exceptions are possible, especially for the sake of emphasis. If a subject or object appears after the verb, or if a subordinate clause occurs after a main clause, it is separated by an intonational break (represented by a comma):

(9) Qa an'ewakw tsovawta, sinom.
in great number were assembled people
A great many people were assembled.

(10) Pas sòosovik navotiwta,
very everywhere be.known,
puma so'qö.
they die.SUBORD(switch-reference)
It is known everywhere that they died.

Nouns inflect for number, case, and possessor. Demonstratives and pronouns inflect for number and case. For number, there are four categories to distinguish: singular (one), dual (two), plural (three or more), and distributive (for various types or in various locations). The singular form is unmarked. The dual form, with suffixed *-t(u-)* or *-m(u-),* is used almost exclusively for animate nouns; inanimates are construed as singular or dual from context. (Things such as clouds, stars, vehicles, and the wind that seem to move of their own accord, as well as sacred things such as places with shrines and developing ears of corn, are treated as animate.) Noun plurals are formed via suffixation, reduplication, suppletion, or combinations of these. Inanimate noun plurals always involve reduplication. Accusative forms are given in parentheses:

(11)

	sing.	du.	pl.
person	sino(t)	sino-t(u-y)	sino-m(u-y)
civilized person	hopi(t)	hopi-t(u-y)	hopìit(u-y)
cloud	oomaw (u-y)	oomaw-t(u-y)	oo'omawt (u-y)
man	taaqa(t)	taaqa-t(u-y)	tàataqt(u-y)
woman	wùuti(t)	wùuti-t(u-y)	momoyam (u-y)
boy	tiyo(t)	tiyo-t(u-y)	tootim(u-y)
old one	wu-y (wuu-kw)	wuu-yo-m (wuu-kw-mu-y)	wuuwuyom (wuu-wu-kw-mu-y)
little spoon	akùwya(t)	(= sg.)	a-'akùwya(t)
Hopi village	Hopìi-ki(t)	(= sg.)	Hopi-ki-ki(t)

Demonstratives and pronouns are identical in the dual and plural:

(12)

	nom.sing.	nom.du./pl.	acc.sing.	acc.dl./pl.
this	i'	ima	it	imuy
that	pam	puma	put	pumuy
that over there	mi'	mima	mit	mimuy
I/we	nu'	itam	nuy	itamuy
you	um	uma	ung	umuy

Verbs also show a range of pluralization types, but with verbs it is often the derivational suffix that undergoes the process:

(13)

	sing./du.	pl.
raise, perfect	aniwna	aniwna-ya
think, consider	wuuwa	wuuwa-ya
bury	aama	am-ya
look for	heeva	hep-ya
be called	maatsiwa	maa-matsiw-ya
pop out of the husk	tsayo	tsayòmti
wear out'	tsàakwa	tsakwàmti
descend	haawi	haani
die	mooki	so'a
sit, dwell	qatu	yeese
arrive	pitu	öki
be dancing	wunima	tiiva
be singing	taw-lawu	taw-lalwa
be grinding coarsely	hàakokin-ta	hàakokin-tota
have a field	paasa'y-ta	paasa'y-yungwa
go along picking corn	a'kiti-ma	a'kiti-wisa
go to pick corn	a'ki-to	a'ki-wisa

Dual subjects take the singular form of the verb. Compare the following (*tuwa* is the singular/dual subject form of the verb and *tutwa* the plural subject form; *itam(u-)* 'we' is identical in the dual and plural):

(14) Nu' kawayot tuwa. I saw a horse.
Itam kawayot tuwa. We (two) saw a horse.
Itam kawayot tutwa. We (several) saw a horse.

Transitive verbs may also require a different form of the verb, depending on whether the object is plural. Such verbs are also marked for plurality of subject.

(15) Nu' itàakawayoy pitsina. I brought our horse in.
Itam itàakawayoy pitsinaya. We (several) brought our horse in.
Nu' itàakawayotuy pitsina. I brought our (two) horses in.
Nu' itàakawaymuy ökina. I brought our (several) horses in.
Itam itàakawaymuy ökinaya. We (several) brought our (several) horses in.

Verbs are inflected for tense (unmarked, future, habitual) as well as subject number. Further, verbs divide into perfective and imperfective stems. In most contexts, unmarked perfectives are construed as past, while unmarked imperfectives can refer to past or present.

Hopi shows an exuberance of derivational suffixing as well as of compounding and noun incorporation into verbs (Hill, 2003). The incorporated noun may be the object of a transitive verb stem:

(16) tap-nina — kill a cottontail (or two) (tap- < taavo 'cottontail', niina 'kill singular/dual object')
tap-qöya — kill cottontails (qöya 'kill plural object')

or the subject of an intransitive:

(17) kwits-wunuptu — for smoke to rise up (kwits- < kwiitsingw 'smoke')
mori-'ùykurùmti — for beans to get planted all over (mori 'beans')
nup-'iwta — for there to be snow on the ground (nup- < nuva 'snow')

Verbs may also incorporate non-objects:

(18) Nu' i-tùmkwivi-y öngaspal-mortoyna.
I my-wild:greens-ACC brine-be:dipping:to:moisten
I'm dipping my wild greens in salt water.

Hopi is unusual in that incorporated nouns may be specific in reference rather than generic, as common in most languages that show such incorporation:

(19) Nu' pakiw-maqto-ni; noqw itam put enang nöönösa-ni.
I fish-go:hunting:for-FUT; so we that:ACC in:addition eat:PL-FUT
I'm going fishing; so we can eat it along with other food. (cf. *paakiw* 'fish')

Modifiers of the incorporated noun may appear as objects of the verb:

(20) Pangqaqw pam naat puuhu-t kwilatots-ma.
from:there he still new-ACC commercially.bought.shoes-PROG
He's coming from there wearing brand-new shoes. (*kwilatotsi* 'commercially bought shoes')

(21) Kikmongwi pas wuuhaqnìiqamu-y mong-'oya.
village.leader very many-ACC leader-put(PL.OBJ)
The village leader sure chose a lot of leaders. (cf. *mongwi* 'leader')

Modifiers may also be incorporated:

(22) puhu-hom-'oyiwta
new-ceremonial.cornmeal-be.offered
for fresh sacred cornmeal to be offered

(23) hihin-hopìi-tuqayta
slight-Hopi-know
know or speak a little Hopi

(24) su'aw-wuko-nup-'iwta
fairly-large-snow-be
for there to be a fairly large amount of snow on the ground

Hopi distinguishes among types of sources of information. Statements based on the direct knowledge of the speaker are unmarked. Statements based on evidence (but not direct experience) are marked by the inferential particle *kur*; statements based on conjecture use the potential modal *kya*; and statements based on secondhand knowledge or hearsay use the quotative particle *yaw*. *Yaw* is especially prevalent in story narration. These evidential particles are relatively free-floating in a sentence; they may occur anywhere before the verb:

(25) Isikwi hovàati. — My meat spoiled.
Isikwi kur hovàati. — My meat seems to have spoiled.
Isikwi kya hovàati. — (I'm afraid) my meat may have spoiled.
Isikwi yaw hovàati. — I hear my meat spoiled.

Dialectally, Hopi divides into three main varieties, differing slightly in pronunciation and vocabulary but with a high level of mutual intelligibility. A prominent phonetic difference resides in the differential development of a feature orthographically represented by the grave accent, as in *wùuti* 'woman'. In Third Mesa speech, such syllables have falling tone. In First Mesa speech and in the speech of the Second Mesa town of Mishongnovi (cf. Whorf, 1946), they end in aspiration. In the speech of the Second Mesa towns of Shipaulovi and Shungopavi, the grave accent feature disappears, such that these syllables are pronounced in the same way as syllables without the grave accent.

Some forms differ between a male speaking and a female speaking:

(26)

	feminine speaker	masculine speaker
very	hin'ur	a'ni
thank you	askwalí	kwakwhá(y)
good/pretty	nukwangw-	loma-
big ones	yangsayoqa	hohoskaya
be a large number	naavinta	kyaasta
it's good	is alí	is ali
too much	is ehe'tihi	is tathi

There exists a rich baby talk vocabulary, used speaking with (or as with) small children. Many baby talk words are phonologically quite distinct from normal speech. An example is *uu'na* 'bite' (non-baby *kuuki*), whose first syllable is pronounced with vocal tension and with the teeth together, a pronunciation not easily handled with the orthography. Sometimes there is no normal speech equivalent: *hòona,* 'dance like a kachina', is perfective; the nearest non-baby equivalent is the imperfective *kakatsina*.

A baby talk term may cover a different range of meaning from anything in normal speech: *Tooto* can refer to any insect (as well as baby animals or birds); there is no adult word that covers insects in general.

There is a seemingly archaic register of song and ritual speech. An example is *oo'oomawutu,* a song form of *oo'omawt* 'clouds', in which a number of phonological processes characteristic of normal speech are suspended: vowel shortening, syncope, and final short vowel deletion. This is reminiscent of the archaicaizing song/poetry register of French, in which the colloquial sound change of dropping the mute *e* is suppressed.

Horacek, Blanka (1913–2001)

S Kürschner, Albert-Ludwigs-Universität, Freiburg im Breisgau, Germany

© 2006 Elsevier Ltd. All rights reserved.

Blanka Horacek was born in Vienna, Austria, on December 22, 1913. She studied German, French, and history at the University of Vienna from 1938 to 1943. In 1943, she received her doctoral degree from the University of Vienna in German, history, and philosophy, with a thesis on Grillparzer and Hormayr. After supplementary studies in Greek, Horacek became a lecturer at Vienna University. As scientific assistant at the Institute of German from 1949 to 1966, she wrote her postdoctoral qualification as a habilitation work on 'Die Kunst der Syntax in Wolframs "Parzival"' (The art of syntax in Wolframs 'Parzival'). She finished the habilitation in 1955 as lecturer in German linguistics and medieval German literature.

Horacek's linguistic work focused on style, syntax, and general grammar. After her postdoctoral thesis, she continued her stylistic studies in a systematic collection of syntax principles in German poetic language, which appeared as a monograph in 1964. In 1966, she supplemented these studies by 'verse principles' in a second edition. By setting the focus on 'art principles,' Horacek defined the special grammar for the language of arts, especially medieval poetic literature. She thereby combined literary interpretation with linguistic description. Horacek also focused on language history: her *Kleine historische Lautlehre* (Little historical phonology) has been one of the elementary basic books for students of German diachronic linguistics.

Horacek was professor of German linguistics and medieval German literature in Vienna from 1968 to 1979. Her focus was never limited to these two broad research topics, however; she also included modern literary studies and their connection to linguistics in her repertoire.

Horacek's list of scientific publications includes two monograph books and the editing of a festschrift for her teacher, Dietrich Kralik. On her main research topics, she published a considerable number of journal articles. She was honored with a festschrift by Ebenbauer, Knapp, and Krämer in 1974. Horacek was a member of the scientific council of the Institute for German Language in Mannheim, Germany. In Vienna, Horacek took part in the Vienna language

Horecký, Ján (b. 1920)

P Štekauer, Presovskej Univerzity, Presov, Slovakia

© 2006 Elsevier Ltd. All rights reserved.

Ján Horecký, born in Stupava, Czechoslovakia, in 1920, university professor and a member of the Learned Society of the Slovak Academy of Sciences, is a unique and prominent personality in the context of Slovak, and more widely, Slavonic and general linguistic studies, demonstrating great talents for creative, penetrating, and in-depth linguistic analysis. He is an author of many monographs and articles, presenting the results of, in many respects, frontier research. Importantly, Horecký has actually obliterated the opposition between 'major' and 'minor' linguistic topics.

No doubt, word formation, conceived of as a component of lexicology, has been the main thread of his linguistic efforts (1959, 1964, 1971, 1989, 1994). His onomasiological model of linguistic sign (1983) underlies a unique model of word formation. Horecký distinguishes between an ideal sign at the system level (including conceptual, semantic, onomasiological, onomatological, and phonological levels) and a communication sign with the ideal sign as its *signifié*. In this respect, Horecký co-developed (with M Dokulil) a new paradigm for the field of word formation that inspired several generations of Slovakists, Germanists, and Anglicists in Slovakia and abroad. While Horecký primarily concentrates on the semantic level, providing a detailed description of the inventory and hierarchy of and the relations between semantic distinctive features (1994), due attention is also paid to comprehensive description of other essential issues such as WF type, the distinction between word formation and morphematic analyses, and the description of individual levels of his dynamic WF model. His theoretical research has also yielded a comprehensive description of the derivational system of Slovak (1989, 2003).

As a general linguist (1978, 1983), Horecký does not explore linguistics in isolation. He sets it in a wider interdisciplinary context, reflecting the nature of the language system, relations between language, human mind, and speech community, and the role of language in cognitive processes. To Horecký, language is primarily a system of verbal behavior.

Horecký is an author of an original theory of literary language. He has developed a stratificational model of Slovak, reflecting the level of *parole*. Much attention in his work is also paid to language culture (2000, 2001).

Horecký established the foundations of mathematical linguistics in the former Czechoslovakia (1969) and has written a large number of articles on lexicography, with special focus on terminology. As a co-author, he also described the linguistic system of the Carpathian Romany (2000).

He is an author of many monographs and articles, presenting the results of, in many respects, frontier research. Importantly, Horecký has actually obliterated the opposition between 'major' and 'minor' linguistic topics.

No doubt, word formation, conceived of as a component of lexicology, has been the main thread of his linguistic efforts (1959, 1964, 1971, 1989, 1994). His onomasiological model of linguistic sign (1983) underlies a unique model of word formation. Horecký distinguishes between an ideal sign at the system level (including conceptual, semantic, onomasiological, onomatological, and phonological levels) and a communication sign with the ideal sign as its *signifié*. In this respect, Horecký co-developed (with M Dokulil) a new paradigm for the field of word formation that inspired several generations of Slovakists, Germanists, and Anglicists in Slovakia and abroad. While Horecký primarily concentrates on the semantic level, providing a detailed description of the inventory and hierarchy of and the relations between semantic distinctive features (1994), due attention is also paid to comprehensive description of other essential issues such as WF type, the distinction between word formation and morphematic analyses, and the description of individual levels of his dynamic WF model. His theoretical research has also yielded a comprehensive description of the derivational system of Slovak (1989, 2003).

As a general linguist (1978, 1983), Horecký does not explore linguistics in isolation. He sets it in a wider interdisciplinary context, reflecting the nature of the language system, relations between language, human mind, and speech community, and the role of language in cognitive processes. To Horecký, language is primarily a system of verbal behavior.

Horecký is an author of an original theory of literary language. He has developed a stratificational model of Slovak, reflecting the level of *parole*. Much attention in his work is also paid to language culture (2000, 2001).

Horecký established the foundations of mathematical linguistics in the former Czechoslovakia (1969) and has written a large number of articles on lexicography, with special focus on terminology. As a co-author, he also described the linguistic system of the Carpathian Romany (2000).

Hornby, Albert Sidney (1898–1978)

H Kishimoto, Kobe University, Kobe, Japan

© 2006 Elsevier Ltd. All rights reserved.

Albert S. Hornby started his career as an English teacher in Oita, Japan, first employed as a high school teacher in 1924. He moved to Tokyo in 1932, invited by Harold E. Palmer, who was then the first director of the Institute for Research in English Teaching (IRET). When Palmer left Japan in 1936, Hornby succeeded him as the director of IRET and held this position until 1942. Hornby's task at this institute was to take over and develop Palmer's verb pattern methods in English language teaching.

One of Hornby's major undertakings in his life was to compile the *Idiomatic and syntactic English dictionary* (ISED; Hornby *et al.*, 1942), which originated from Palmer's project, and it was published by the Japanese publisher Kaitakusha in 1942, shortly after Hornby was forced to leave Japan during World War II. Some of the features of the dictionary especially designed for learners of English include a clear indication of verb patterns, and a distinction between countable and uncountable nouns. In 1948, this dictionary was reissued under the new title *A learner's dictionary of current english* (ALDCE) by Oxford University Press (Hornby *et al.*, 1948). Further revised versions enriching its contents appeared as *The advanced learner's dictionary of current English* (Hornby *et al.*, 1963), and as *Oxford advanced learner's dictionary of current English* (Hornby, *et al.*, 1974).

Hornby's other major contribution to English language teaching was his acting as a founding editor of *English language teaching*, which was then a small-scale publication issued by the British Council. In the 1950s, Hornby published a number of textbooks and handbooks for English language teaching. *A guide to patterns and usage in English* (Hornby, 1954) was the most influential pedagogical grammar of the time. The novelty of this book is the classification of English sentences into 25 patterns, with ample examples illustrating the grammar. Other widely known books by Hornby include the English language textbook *Oxford progressive English for adult learners* in three volumes (so-called 'Hornby course'; Hornby, 1954–1956) and the teacher's practical handbook *The teaching of structural words and sentence patterns* in four volumes (Hornby, 1959–1966).

In 1961, Hornby established *The Hornby Educational Trust*, by donating a large portion of his royalty income from the dictionaries and the textbooks. The Trust came into operation in 1968, supporting overseas teachers who study the English language in the United Kingdom, and making funds available to help provide training for teachers of English, especially in developing countries and elsewhere where there is need for funding. In 1976, Hornby was appointed a fellow of the University College London, and in 1977, he received an honorary degree from the University of Oxford in recognition of his significant contribution to English language teaching.

Hornung, Maria (b. 1920)

H-D Pohl, University of Klagenfurt, Klagenfurt, Austria

© 2006 Elsevier Ltd. All rights reserved.

Maria Hornung was born in Vienna on May 31, 1920 (maiden name Jechl). After her final high-school examination in 1938 she went to Vienna University to study German, English, and Romanic philology. She wrote her Ph.D. dissertation on a literary theme (Hornung, 1942), but soon developed an interest in Austrian–German dialectology and in April of 1942 she got a job ('war substitute') at the Wiener Wörterbuchkommission (Viennese Dictionary Commission) of the Austrian Academy of Sciences in Vienna. This was the beginning of her scientific career. Dialectology has been her main activity since 1948, when she was invited by the head of the Wörterbuchkanzlei (Dictionary Office), Anton Pfalz (1885–1956), to cooperate in this institution, because she – though born and raised in Vienna – spoke the Tyrolean dialect very well. East Tyrolia was her habilitation subject (Hornung, 1964). In 1964 Maria Hornung became a university teacher, and from 1969 to 1985 was professor of German linguistics at Vienna University.

Anyone researching the Bavarian dialects of Austria will find in the relevant scientific literature not only the name of the great Austrian scholar of dialectology and onomastics Eberhard Kranzmayer (1897–1975), but also the name of his eminent disciple and scientific successor, Maria Hornung. She devoted her life to Austrian dialectologic and onomastic studies, including the linguistic German enclaves in Northern Italy and Slovenia, colonized from Southern Austria in the Middle Ages. Her researches in the dialects of language enclaves are among her grand achievements. Together with her husband Herwig Hornung (d. 1987) she founded the Österreichisches Sprachinselmuseum (Austrian Language Enclaves Museum) in 1982. This museum contains many scientific documents and especially numerous folkloristic exhibits showing the life in these enclaves.

In her very personal article 'It began in Mörtschach: how I became an explorer of Austrian dialects' (Hornung, 1989) she describes her first research in the Mölltal (Möll Valley, Carinthia) during World War II and the rural life in this region at that time. The Mölltal has many relations to East Tyrolia. In this part of Austria she wrote her habilitation, *East Tyrolean Dialectology* (Hornung, 1964). This book shows her profound knowledge of Tyrolean dialects and folklore. Together with Franz Roitinger, she published the book *Our Dialects* (Hornung and Roitinger, 1950; new edition, 2000). Together with Alfred Ogris she prepared the edition of Primus Lessiak and Eberhard Kranzmayer's lexical and grammatical researches on the German dialect of Sorica and Rut in Slovenia (Kranzmayer and Lessiak, 1983). Her main work in the field of linguistic enclaves is her *Dictionary of Pladen/Sappada* (Hornung, 1972). She was also the editor of the *Gottschee Dictionary* (Tschinkel, 1973–1976).

Maria Hornung has written some articles about her teacher Eberhard Kranzmayer and she edited his Ph.D. dissertation on Cimbro (Kranzmayer, 1981–1985), and she collaborated on two festschrifts for him. In the volume *Austrian German* Maria Hornung wrote the article on the correct pronunciation of names in Austria (Hornung, 1988). Her contributions to the *Bavarian–Austrian Dictionary* (WBÖ) and the *Österreichisches Wörterbuch* (ÖWB) helped document the whole Austrian–German lexical stock. A result of many years of research is her *Vienna Dialect Dictionary* (Hornung, 1998) with etymological notes.

Householder, Fred W., Jr. (1913–1994)

S-H Seong, University of Bonn, Germany

© 2006 Elsevier Ltd. All rights reserved.

Fred Walter Householder (1913–1994) was born in Wichita Falls, Texas, and grew up in Chepachet, Rhode Island. In 1933, he entered Columbia University for graduate studies in linguistics and received his doctorate in 1941. Householder was trained especially in the areas of classical philology, Sanskrit, and phonetics at Columbia. His teacher, Victor Oswald, is said to have had the strongest influence on his linguistic training, in which Householder was exposed to the structuralist writings of Trubetzkoy and Jakobson.

Upon completion of his doctorate, Householder taught at Columbia until 1948. During this period he wrote a Modern Greek (Greek) military dictionary with the help of Eliopoulos in the Armed Forces Institute, where language dictionaries and textbooks were produced. This was the place in which he came to know such linguists as Bill Austin, Henry Lee Smith, Morris Swadesh, Thomas Sebeok, and Allen Walker Read. After two years of teaching at Allegheny College Householder eventually secured a position at Indiana University in Bloomington and was named a research professor of classics and linguistics in 1965 and served as chairperson of the Department of Linguistics from 1974 to 1980.

Householder's prime teaching and research interests centered on American structuralism coupled with the heritage of European (Greek and Latin) and traditional philological studies. American structuralism, which shaped the academic milieu in the discipline of linguistics at the time of Householder, was the product of the body of work published in the United States in the 1940s and 1950s, and this trend was heavily influenced by Leonard Bloomfield's work *Language* (1933).

In literature, American structuralism is also characterized as taxonomic, descriptive, and strictly empirical. If linguistics were to be scientific, it must make statements only about observable phenomena. According to Householder's view, most of the grammars of natural languages are "in the form of open analogical chains with general instructions to extend." So the grammar of a language, if it is to be an ideally economic model, would consist of rules and lists. This way of analyzing language data is clearly visible in Householder's *Linguistic speculations* (1971), in which he utilizes the concept of distinctive feature as a modus operandi when it comes to explaining the phonological oppositions of word sets. Thus, he writes "[t]he point here is that it is in terms of such features (or, more basically, the analogies which they represent) that we can give an answer to the question 'Is this the same word as that or a

In literature, American structuralism is also characterized as taxonomic, descriptive, and strictly empirical. If linguistics were to be scientific, it must make statements only about observable phenomena. According to Householder's view, most of the grammars of natural languages are "in the form of open analogical chains with general instructions to extend." So the grammar of a language, if it is to be an ideally economic model, would consist of rules and lists. This way of analyzing language data is clearly visible in Householder's *Linguistic speculations* (1971), in which he utilizes the concept of distinctive feature as a modus operandi when it comes to explaining the phonological oppositions of word sets. Thus, he writes "[t]he point here is that it is in terms of such features (or, more basically, the analogies which they represent) that we can give an answer to the question 'Is this the same word as that or a

different one' (. . .)" (Householder, 1971: 67). In chapters 9 and 10, Householder discusses 'phonemes and distinctive features' extensively, based on the procedures of classification and segmentation. Thus, the contrast-based phoneme is treated as a primitive. He sets out the present research position while questioning some underlying assumptions and testing the adequacy of the available descriptive theories of that time. In this respect, it is natural that one finds clear theoretical differences between Householder and Chomsky in terms of interpreting the relations between phones and phonemes (Householder, 1971: 199, 1965b).

Given the nonempirical solutions of the transformational grammar, Householder expresses his strong and objective disagreement to Chomsky and Halle's generative phonology, in which they attempted to do away with the phonemic theory in support of the economy of phonological derivation. According to Chomsky and Halle, phonemic transcriptions are 'regularized phonetic representations,' and the fundamental criterion of phonemic analysis on the part of the American structuralism is 'devoid of any theoretical significance.' On the contrary, Householder demonstrates that feature matrix notation is not economical than phonemic notation, and that the feature matrix-based classes are not always natural. This well-known debate also involves some methodological and philosophical issues in linguistics. This controversy has become one of the well-known good entrées to the theoretical issues in the literature.

Post-Bloomfieldian way of treating the linguistic data, i.e., a distributional analysis, is also observed in one of Householder's articles titled 'Some facts about who and whom' (1986), in which the relative frequencies of occurrence of the four basic types of human objective relative clauses in English are discussed. In the literature, Householder is also often cited for having drawn a distinction between 'hocus pocus' linguistics and 'God's Truth' linguistics in his review of Harris's *Method* (1952).

Householder is also well known for his works on the classics. He wrote on Homer, Aristotle, Dionysius Thrax, Apollonius Dyscolus, and Lucian. With his *Reference grammar of literary Dhimotiki* (with K. Kazazis and A. Koutsoudas), he made a significant contribution to the Modern Greek studies as well.

Even though Householder was originally an Indo-Europeanist, he became extensively acquainted with Turkish and Azerbaijani and even had opportunities to supervise dissertations on Azerbaijani, Hungarian, Finnish, Korean, Japanese, Classical Mongolian and Classical Manchu (Manchu). Householder also served the LSA (Linguistic Society of America) on many occasions and became the vice president (1980) and the president of the Society (1981). He was also elected to the prestigious American Academy of Arts and Sciences.

Hovland, Carl Ivor (1912–1961)

W A Hass, St Peter, MN, USA

© 2006 Elsevier Ltd. All rights reserved.

Carl Ivor Hovland was a pioneer psychological researcher in the experimental study of communication and propaganda.

Born in Chicago of Scandinavian Lutheran parents, Hovland received a B.A. (1932) and M.A. (1933) from Northwestern University, and a Ph.D. (1936) in psychology from Yale University under the mentorship of learning theorist Clark Hull. He stayed on the psychology faculty at Yale's Institute of Human Relations, leaving during World War II to engage in military research. He collaborated with moviemaker Frank Capra in the production of the documentary film series 'Why we fight,' shown to about 15 million new American soldiers and evaluated by Hovland's team of researchers. He then returned to Yale, became chair of the Psychology Department, and continued his empirical studies in persuasion and attitude change. His early death, shortly after his wife's, occurred after he himself was diagnosed with cancer.

Using before-after questionnaires, he was able to show that the propaganda films increased soldiers' knowledge of the background of the war, and, to a lesser extent, their attitudes favoring it, but had no measurable effects on their motivation to serve as soldiers. Two-sided presentations (including both pro and con aspects) turned out to be more effective with more intelligent or highly educated soldiers, as well as with soldiers who did not initially agree with the government's position. He discovered a 'sleeper effect,' in which a message may have a delayed impact on the recipient, even after the source of the message may have been forgotten. Recipients' mood also affected persuasibility, with groups provided with soda and peanuts showing more attitude change than groups without snacks. He also investigated the effects of source credibility, which tended to interact with the sleeper effect, as well as the effectiveness of fear appeals, which tended to produce more change if mild (rather than strong).

He did not show any particular interest in the structure of language, even though verbal components loomed large in his research and might well have led him to question how language itself was involved in attitude formation and change. His prolific line of research has inspired myriad basic and applied studies of mass communication in general and advertising in particular.

Hsu Shen (ca. 58–147 A.D.) developed a method for organizing dictionaries of the Chinese language. His main work, the *Shuowen jiezi* (Explaining Simple and Compound Characters), set a standard that was used, with modifications, for centuries since it was first written about 120 A.D.

A Chinese dictionary is arranged differently than dictionaries of languages with alphabetic orthographies. An alphabet is a system of symbols reproducing, more or less accurately, the sound of words. Words can be organized in a list in alphabetical order. No equivalent system existed in Hsu Shen's day. Despite modern attempts to 'alphabetize' Chinese, a purely alphabetical system does not work for Chinese dictionaries because of the large degree of homophony in the Chinese language.

Hsu Shen's solution to this problem was to create a system which categorized the *zi* (characters) by radical. A radical is a portion of a character that, in some way, allows the pronunciation or meaning of the character to be discerned. Hsu Shen realized that it is not enough to simply list the *zi* by radical. Each group of characters needs an order of its own. If a group of characters is related by all having the radical *yi,* how should these *yi*-characters be organized? Each character was written in a strict, traditional way, with a fixed number of brushstrokes. Hsu Shen saw that they could be ordered by stroke count, with the simpler, probably more common, characters at

the beginning of the list, followed by more complex, probably less common, characters. Within stroke count groups, the order is, essentially traditional.

Hsu Shen's radical groups numbered as high as 800. Today, there are around 200 in use, depending on the dictionary. Over the centuries, Hsu Shen's indexing system has been simplified for ease of use. Most modern dictionaries use the simplified radical list developed in the Ming Dynasty (c. 1615). Several dictionaries prior to the Ming had reduced the radical count from Hsu Shen's approximately 800.

Hsu Shen also included etymological information in the belief that this would be a useful memory aid. A current dictionary that provides this type of information is *Chinese characters – a genealogy and dictionary*.

Hsu Shen's method has proved useful but raises its own problems. Many Chinese characters contain phonetic information, but the phonetic information may refer to pronunciations that are no longer current. Using stroke counts depends heavily on knowledge of traditional writing methods and on the fonts used. Small font sizes often make accurate stroke counts difficult, if not impossible, for complex characters. The Chinese language has prompted hosts of reform methods, none of which have achieved universal acceptance. Simplification schemes run into cultural opposition as well as the flexibility of the language itself. There is no theoretical limit to the number of characters. In a sense, all dictionaries are special-purpose works.

Human Language Processing: Connectionist Models

L Onnis, Cornell University, Ithaca, NY, USA
M Christiansen, Cornell University, Ithaca, NY, USA
N Chater, University of Warwick, Coventry, UK

© 2006 Elsevier Ltd. All rights reserved.

Connectionist psycholinguistics is an emerging approach to modeling empirical data on human language processing using connectionist computational architectures. Over the last 20 years, a wide range of psycholinguistic phenomena have been modeled, such as speech processing, impaired and normal reading, aphasic word production, and structural priming in sentence production. In this article, we will focus on syntax, and especially on the theoretical relationship between traditional notions in syntax (constituency, structure dependency, recursion) and connectionist networks, which do not appear to make reference to these notions intrinsically. For an overview of other aspects of connectionist language processing, see Christiansen and Chater (2001) and Rohde and Plaut (2003).

Connectionist models, or neural networks, are neurally inspired devices based on numerical computation, rather than symbolic manipulation. They are formed by several simple processing units called nodes, which mimic the activity of single neurons. Each node is excited or inhibited by information coming from other units to which it is connected. A set of homogeneous nodes that collectively represents some information is often called a layer. For instance, there could be a phoneme layer, a word layer, and so on. A popular architecture in connectionist psycholinguistics is the feed-forward network (**Figure 1**), where an input layer receives signals (e.g., raw words) from outside the network, an output layer sends signals to outside the network, and an intermediate layer of so-called hidden units does not directly connect to the outside of the network. Hidden unit layers are often considered the internal states that

Connectionist psycholinguistics is an emerging approach to modeling empirical data on human language processing using connectionist computational architectures. Over the last 20 years, a wide range of psycholinguistic phenomena have been modeled, such as speech processing, impaired and normal reading, aphasic word production, and structural priming in sentence production. In this article, we will focus on syntax, and especially on the theoretical relationship between traditional notions in syntax (constituency, structure dependency, recursion) and connectionist networks, which do not appear to make reference to these notions intrinsically. For an overview of other aspects of connectionist language processing, see Christiansen and Chater (2001) and Rohde and Plaut (2003).

Connectionist models, or neural networks, are neurally inspired devices based on numerical computation, rather than symbolic manipulation. They are formed by several simple processing units called nodes, which mimic the activity of single neurons. Each node is excited or inhibited by information coming from other units to which it is connected. A set of homogeneous nodes that collectively represents some information is often called a layer. For instance, there could be a phoneme layer, a word layer, and so on. A popular architecture in connectionist psycholinguistics is the feed-forward network (Figure 1), where an input layer receives signals (e.g., raw words) from outside the network, an output layer sends signals to outside the network, and an intermediate layer of so-called hidden units does not directly connect to the outside of the network. Hidden unit layers are often considered the internal states that

Figure 1 A standard feed-forward network containing three layers of units. Information flows bottom-up from input to output units. These types of networks are normally trained using the back-propagation algorithm, which minimizes the discrepancy between the network's actual and desired output.

represent the knowledge acquired by the network at the end of training. Information flows from input to output and training proceeds by adjusting the weights between single units until the network produces a desired output (for instance, the production of the correct word syntactic category in a given context).

Two aspects of neural networks are particularly interesting for syntactic processing: first, networks **learn** to perform some specific task, e.g., process an English sentence, from being exposed to relatively unanalyzed raw input, such as a sequence of words. This feature makes them suitable for explaining a great deal of language learning and language processing in a psychologically plausible manner. Secondly, the knowledge of the networks is not represented in any explicit way, but rather emerges as a pattern of neuronal activity between the interconnected nodes, in a parallel distributed processing fashion. This is particularly interesting because it contrasts with more traditional symbolic views in cognitive science, suggesting that humans process sentences by transforming representations according to sets of rules. For instance, a representation of the sentence *the girl liked a boy*, requires the constituents *the*, *a, girl, boy*, *liked*, and an explicit representation of the syntactic relationships between these constituents. The rules of syntax govern how constituents can be combined together, allowing, for instance, *the boy liked a girl* as a legal sentence, but not *boy girl a liked the*. Phrase structure rules describe the relationship between constituents in the above sentence:

S → NP VP
NP → (det) N
VP → V (NP)

Besides such constituent structure, to capture the full generativity of human language, recursion needs to be introduced, for instance by adding a new rule that adds a potential prepositional phrase (PP) to the NP:

NP → (det) N (PP)
PP → prep NP

These rules are recursive because the expansion of the right-hand sides of each can call the other. For example, the complex NP *the flowers in the vase* has the simple NP *the vase* recursively embedded within it. Because this process can be applied arbitrarily often, constructions of arbitrary complexity can in principle be generated. Constituency and recursion are some of the most fundamental concepts in linguistics. Since both are defined in terms of relations between symbols, symbolic models of language processing therefore incorporate these properties by fiat. In this article, we discuss how constituency, structure dependency, and recursion may fit into a connectionist framework, and the possible implications this work may have for linguistics and psycholinguistics.

Constituency

Connectionist models can address constituency in three increasingly radical ways. First, some models – especially early ones – are implementations of symbolic language processing models in neural hardware; for example, Fanty's (1986) network implementation of a context-free grammar contains explicit representations of the constituent structure of a sentence in just the same way as a nonconnectionist implementation of the same model would have. Connectionist implementations of this kind provide feasibility proofs that traditional symbolic models of language processing are compatible with a 'brain-style' computational architecture, although they add little that is new to the treatment of constituency. The remaining two classes of connectionist models actually **learn** to process constituent structure, rather than having this ability hardwired. One approach is to have a network learn from input 'tagged' with information about constituent structure. Kim *et al.* (2002) train a network to map a combination of orthographic and cooccurrence-based semantic information about a word onto a structured representation encoding the minimal syntactic environment for that word. With an input vocabulary consisting of 20 000 words, this model has an impressive coverage, and can account for certain results from the psycholinguistic literature

concerning ambiguity resolution in sentence processing. Henderson and Lane (1998) provide a model known as a simple synchrony network trained to parse sentences preencoded as parts of speech. The network takes the part of speech tags for the sentence constituents as input and is trained to output the parse tree fragment of a given constituent when that constituent is queried. The network learns to parse a corpus of written English reasonably well. However, because in these models constituent structure is compiled either into the input or the output representations, this style of model does not offer any fresh insight into how the linguistic constituency might operate, based on connectionist principles.

The third class of connectionist models addresses the more ambitious problem of learning the constituent structure of a language from untagged linguistic input. Such models have the potential to develop a new or unexpected notion of constituency, and hence may have substantial implications for theories of constituency in linguistics and psycholinguistics.

To understand how the more radical connectionist models address constituency, we can divide the problem of finding constituent structure into two interrelated parts: segmenting the sentence into chunks that correspond, to some extent, to linguistic constituents; and categorizing these units appropriately. The first problem is an aspect of the general problem of segmenting speech into appropriate units (e.g., phonemes, words, etc.) and more generally is an aspect of perceptual grouping. The second problem regards the general problem of classifying linguistic units, for instance, recognizing different classes of phonemes or establishing the parts of speech of individual lexical items. The segmentation and classification problems need not be solved sequentially. Indeed, there may be mutual influence between the decision to segment a particular chunk of language and the decision that it can be classified in a particular way. Nonetheless, it is useful to keep the two aspects of the analysis of constituency conceptually separate.

It is also important to stress the difference between the problem of assigning constituent structure to novel sentences, where the language is known, and the problem of acquiring the constituent structure of an unknown language. Statistical symbolic parsers are able to make some inroads into the first problem (Charniak, 1993). For highly stylized language input, and given a prestored grammar, they can apply grammatical knowledge to establish one or more possible constituent structures for novel sentences. But symbolic methods are much less advanced in acquiring the constituent structure of language, because this requires solving the hard problem of learning a grammar from a set of sentences generated by that grammar. It is therefore in relation to the **acquisition** of constituency that connectionist methods, with their well-developed learning methods, have attracted the most interest.

We begin by focusing on the problem of classifying, rather than segmenting, the linguistic input. One connectionist model (Finch and Chater, 1993) learns parts of speech of individual words by clustering words together on the basis of the immediate linguistic contexts in which they occur. The rationale is based on the replacement test: if two words are observed to occur in highly similar immediate contexts in a corpus, they probably belong to the same syntactic category. Finch and Chater used a single-layer network with Hebbian learning to store cooccurrences between target words and their immediate neighbors, such that each target word was associated with a vector representing the contexts in which it typically occurs. A competitive learning network classified these vectors, grouping together words with similar syntactic categories. This method is able to operate over unrestricted natural language, in contrast to most symbolic and connectionist models. From a linguistic perspective, the model slices lexical categories too finely, producing, for example, many word classes that correspond to nouns or verbs. On the other hand, the words within a class tend to be semantically related, which is useful from a cognitive perspective. The same method can be extended to classify sequences of words as NPs, VPs, etc. An initial classification of words is used to recode the input as a sequence of lexical constituents. Then short sequences of lexical constituents are classified by their context, as before. The resulting groups of phrases (e.g., Determiner-Adjective-Noun) are readily interpretable as NPs, VPs, PPs, and so on, but again these groupings are too linguistically restrictive (i.e., only a small number of NPs are included in any particular cluster). Moreover, this phrasal level classification has not yet been implemented in a connectionist network.

A different attack on the problem of constituency involves training simple recurrent networks (SRNs) on linguistic input (Elman, 1990). An SRN involves a crucial modification to a feed-forward network: the current set of hidden unit values is 'copied back' to a set of additional input units, and paired with the next input to the network (**Figure 2**). The current hidden unit values can thus directly affect the next hidden unit values, providing the network with a memory for past inputs. This enables it to tackle online sentence processing, where the input is revealed sequentially over time.

Segmentation into constituents can be achieved in two ways by an SRN trained to **predict** the next input.

Figure 2 A simple recurrent network (SRN) is essentially a standard feed-forward network equipped with an extra layer of so-called context units. At each time step, an input propagates through the hidden units to the outputs (solid arrows). The hidden unit activation at the previous time step is copied back to the context layer (dashed arrows) and paired with the current input (solid arrows). Thus the hidden units influence the processing of subsequent inputs, providing a limited ability to deal with sequential inputs.

One is based on the assumption that predictability is higher within constituents than across constituent boundaries, and hence that high prediction error indicates a boundary. This method has been advocated as potentially applicable at a range of linguistic levels (Elman, 1990), but in practice has only been successfully applied on corpora of unrestricted natural language input in finding word boundaries (Cairns *et al.*, 1997). Even here, the prediction strategy is a very partial cue to segmentation. If the network is provided with information about naturally occurring pauses between utterances (or parts of utterances), an alternative method is to assume that constituent boundaries occur where the network has an unusually high expectation of an utterance boundary. The rationale is that pauses tend to occur at constituent boundaries and hence the prediction of a possible utterance boundary suggests a constituent boundary may have occurred. This approach seems highly applicable to segmenting sentences into phrases, but has also primarily been used for finding word boundaries in real corpora of language, when combined with other cues (Christiansen *et al.*, 1998).

So far, we have considered how SRNs might find constituents. But how well do they classify constituents? At the word level, cluster analysis of hidden unit activations shows that, to some extent, the hidden unit patterns associated with different word classes group naturally into syntactic categories, for SRNs trained on simple artificial grammars (Elman, 1990). These results are important because they show that even though the SRN may not learn to classify constituents **explicitly**, it is nevertheless able to use this information to process constituents appropriately (see Fodor and Pylyshyn, 1988 versus van Gelder, 1998). Another way of assessing constituency learning is to see if networks generalize to predict novel sentences of a language. The logic is that to predict successfully, the SRN must exploit linguistic regularities that are defined across constituents, and hence develop a notion of constituency to do so. However, Hadley (1994) points out that this type of evidence is not compelling if the novel sentences are extremely similar to the network's training sentences. He suggested that, to show substantial evidence for generalization across constituents, the network should be able to handle novel sentences in which words appear in sentence locations where they have **not** previously occurred. For example, a novel sentence might involve a particular noun in object position, where it has previously occurred only in subject position. This property of the human brain, which Fodor and Pylyshyn (1988) call systematicity, captures the idea that if one can understand the sentence *Bob loves Mary* one can also understand *Mary loves Bob*; the underlying knowledge that supports understanding of the first sentence enables understanding the second. Hence, to generalize effectively, the network must presumably develop some abstract category of nouns.

Christiansen and Chater (1994) addressed Hadley's challenge presenting evidence that connectionist models are able to attain strong generalization. In their training corpus, the noun *boy* was prevented from ever occurring in a noun phrase conjunction (i.e., noun phrases such as *John and boy* and *boy and John* did not occur). During training, the SRN had therefore only been presented with singular verbs following *boy*. Nonetheless, the network was able to correctly predict that a plural verb must follow *John and boy* as prescribed by the grammar. In addition, the network was still able to correctly predict a plural verb when a prepositional phrase was attached to *boy* as in *John and boy from town*, providing even stronger evidence for strong generalization. In contrast, when the SRN was presented with ungrammatical lexical items in the second noun position, as in *John and near*, it did not activate the plural nouns. Instead, it activated lexical items that were not grammatical given the previous context. This suggests that the SRN is able to make nonlocal generalizations based on the structural regularities in the training corpus (see Christiansen and Chater, 1994 for further details). If the SRN relied solely on local information it would not have been able to make correct

predictions in either case. Thus, the network demonstrated sophisticated generalization abilities, ignoring local word cooccurrence constraints while appearing to comply with structural information at the constituent level. Additional evidence of strong generalization in connectionist nets are found in Niklasson and van Gelder (1994) (but see Hadley, 1994 for a rebuttal).

Another strong test of generalizations that connectionist models seem to fail concerns equivalence relations: Marcus (1998) trained an SRN on sentences like *A rose is a rose* or *A tulip is a tulip*, but when given a novel sentence fragment like *A blicket is a*. . ., the SRN could not predict that *blicket* was going to be the next word because it activated all the words that it had seen in this sentence position (e.g., *rose*, *tulip*, etc.). This suggests that it did not develop abstract variable-based frames like *a X is a X*, where *X* is a variable that can be bound to any word. In reply to Marcus, Chang (2002) argued that a model of sentence production could generalize well if the input message was encoded in several separate representations that were linked together. Chang's architecture had one pathway for representing the mapping of object semantics to word forms and another for representing and mapping objects (and the words that describe them) into appropriate sentence positions. The model contained a bank of units representing event roles (agent, patient, etc.) that feeds onto a layer of lexical units (e.g., DOG, CAT, etc.). This way the model could represent the different roles of a word, say *dog*, in various events while activating a common semantics that all dogs have. Semantic units connected to word label units that represented the phonetics of each word, allowing the learning of a word label for each meaning. Since there was only one set of semantic units for different event role units, learning the mapping of the semantic feature DOG to the word label *dog* allowed the model to generalize this word to other event roles. Hence, even if the model had only experienced the sentence *the dog chases the cat*, it was able to generalize and produce a novel sentence *the cat chases the dog*.

Rohde (2002) developed a model (CSCP) that performs both comprehension and production of complex, multiclausal sentences using a larger corpus than previous models. In this respect, neural networks promise to scale up to real samples of natural language. The model deals with several sentence comprehension and production phenomena that involve discovery of constituent structure such as multiple verb tenses and voices, adverbs and adjectives, prepositional phrases, relative and subordinate clauses, and sentential complements. As in Chang (2002), the network has a semantic component, which is used to help the net predict the next word. The semantic component is also used to produce a word. When a word is selected for production, it is fed back into the comprehension input and the model proceeds to produce the next word, and so on. Therefore the model also claims that language production is learned primarily by formulating implicit predictions while attempting to comprehend one's language.

In this discussion, it must be noted that connectionist models do not mirror classical constituency precisely. That is, they do not derive rigid classes of words and phrases that are interchangeable across contexts. Rather, they divide words and phrases into clusters without precisely defined boundaries and treat them differently depending on the linguistic contexts in which they occur. This context-sensitive constituency can be viewed either as the undoing of connectionist approaches to language, or their radical contribution. The potential problem with context-sensitive constituency is the productivity of language: to take Chomsky's famous example, how do we know that the sentence *colorless green ideas sleep furiously* is syntactically correct, except by reference to a context-**insensitive** representation of the relevant word classes? This seems necessary, because each word occurs in a context where it has rarely been encountered before. But Allen and Seidenberg (1999) argue that this problem may not be fatal for context-sensitive notions of constituency. They trained a network to mutually associate two input sequences: a sequence of word forms and a corresponding sequence of word meanings. The network was able to learn a small artificial language successfully: it was able to regenerate the word forms from the meanings and vice versa. Allen and Seidenberg then tested whether the network could recreate a sequence of word forms presented to it, by passing information from form to meaning and back. Ungrammatical sentences were recreated much less accurately than grammatical sentences, and the network was thus able to distinguish grammatical from ungrammatical sentences. Importantly, this was true for sentences in which words appeared in novel grammatical combinations, as specified by the systematicity criterion, and as exampled in Chomsky's famous sentence. Thus, the context-sensitivity of connectionist constituency may not rule out the possibility of highly creative and novel use of language, because abstract relations may be encoded at a semantic level, as well as at the level of word forms.

If the apparent linguistic limitations of context-sensitive constituency can be overcome, then the potential psychological contribution of this notion is enormous. First, context-sensitivity seems to be the norm, throughout human classification. Second, much data

on sentence processing can be explained naturally by assuming that constituents are represented in a fuzzy and context-bound manner.

Structure Dependency

A linguistic concept intimately tied to constituency is structure dependency, the notion that grammatical knowledge relies on the structural relationships between constituents, rather than on the linear sequence of items. One of the fiercest arguments leveled at distributional models of learning (of which neural networks can be seen as an instantiation) concerns the uninformativeness of such mechanisms for detecting linguistically relevant properties (Pinker, 1984). Pinker argued that the most relevant properties of language are abstract, such as phrase structure configurations, grammatical relations, and syntactic categories, whereas information contained in raw input pertains to serial position, adjacency, and co-occurrence relations among words. To the extent that connectionist models, and in particular SRNs, process information simply relying on the linear sequencing of linguistic elements (at any level of analysis, phonemes, morphemes, words, etc.), they would seem doomed to fail to capture structure dependency. Reali and Christiansen (in press) demonstrated that SRNs could master a classic example of structure dependency in English, auxiliary fronting. In the generative linguistics framework, declaratives are turned into questions by fronting the correct auxiliary. For example, to turn the declarative form *The man who is hungry is ordering dinner*, it is correct to front the main clause auxiliary as in (1a), but fronting the subordinate clause auxiliary produces an ungrammatical sentence as in (1b) (Chomsky, 1980).

(1a) *Is the man who is hungry ordering dinner?*
(1b) **Is the man who hungry is ordering dinner?*

A structure-independent rule would move the first *is*, but the correct structure-dependent rule involves only the movement of the *is* from the main clause. Because children do not erroneously move the first *is* to the front of the sentence (Crain and Nakayama, 1987), and because they receive too little direct evidence for inferring correct auxiliary fronting (e.g., Chomsky, 1980), it has been claimed that structure dependency could not be learned from positive evidence by an associative mechanism. Reali and Christiansen trained SRNs to predict the next lexical category from a corpus of child-directed speech that contained no relevant examples of correct auxiliary fronting. The networks, tested on completely novel sentences, produced more accurate predictions for grammatical test sentences such as *Is the boy who is hungry nearby?* than for ungrammatical sentences, such as **Is the boy who hungry is nearby?* The prediction of the well-formed relative clause continuation, V (i.e., *is*), was highly preferred over the ill-formed version, ADJ (i.e., *hungry*). This pattern of predictions reflected the networks' sensitivity to the statistical properties of the corpus. The networks distinguished chunks of lexical categories that were more frequent in the training input from less frequent ones (i.e., the lexical categories corresponding to PRON V ADJ [*who is hungry*] vs. PRON ADJ V [*who hungry is*]). This work suggests that the networks were sensitive to the indirect statistical evidence present in the corpus, developing an appropriate bias toward the correct forms of AUX-questions without having a built-in rule for question formation.

Recursion

As with constituency, connectionist models have dealt with recursion in three increasingly radical ways. The least radical approach is to hardwire recursion into the network (e.g., as in Fanty's [1986] implementation of phrase structure rules) or to add an external symbolic (first-in-last-out) stack to the model (e.g., as in Kwasny and Faisal's [1990] deterministic connectionist parser). In both cases, recursive generativity is achieved entirely through standard symbolic means, and although this is a perfectly reasonable approach to recursion, it adds nothing new to symbolic accounts of natural language recursion. The more radical connectionist approaches to recursion aim for networks to *learn* to deal with recursive structure. One approach is to construct a modular system of networks, each of which is trained to acquire different aspects of syntactic processing. For example, Miikkulainen's (1996) system consists of three different networks: one trained to map words onto case-role assignments, another trained to function as a stack, and a third trained to segment the input into constituent-like units. Although the model displays complex recursive abilities, the basis for these abilities and their generalization to novel sentence structures derive from the configuration of the stack network combined with the modular architecture of the system rather than being discovered by the model.

The most radical connectionist approaches to recursion attempt to learn recursive abilities with minimal prior knowledge built into the system. In this type of model, the network is most often required to discover both the constituent structure of the input as well as how these constituents can be recursively assembled into sentences. As with the similar approach to constituency described above, such models may provide new insights into the notion of recursion in human language processing.

Before discussing these modeling efforts, we need to assess to what extent recursion is observed in human language behavior. It is useful to distinguish simple and complex recursion. Simple recursion consists in recursively adding new material to the left (e.g., the adjective phrases (AP) in *the grey cat* → *the fat grey cat* → *the ugly fat grey cat*) or right (the PPs in *the flowers in the vase* → *the flowers in the vase on the table* → *the flowers in the vase on the table by the window*) of existing phrase material. In complex recursion, new material is added in more complicated ways; for example, through center-embedding of sentences (*the chef admired the musicians* → *the chef who the waiter appreciated admired the musicians*). Psycholinguistic evidence shows that people find simple recursion relatively easy to process, whereas complex recursion is almost impossible to process with more than one level of recursion. For instance, the following sentence with two levels of simple (right-branching) recursion, *The busboy offended the waiter who appreciated the chef who admired the musicians* is much easier to comprehend than the comparable sentence with two levels of complex recursion, *The chef who the waiter who the busboy offended appreciated admired the musicians*. Because recursion is built into symbolic models, there are no intrinsic limitations on how many levels of recursion can be processed. Instead, such models must invoke extrinsic constraints, such as the competence/performance distinction, to accommodate the human performance asymmetry on simple and complex constructions. The radical connectionist approach models human performance directly without the need for extrinsic performance constraints.

The SRN model by Elman (1991) was perhaps the first connectionist attempt to simulate human behavior on recursive constructions. This network was trained on sentences generated by a small context-free grammar incorporating center-embedding and a single kind of right-branching recursive structure. In related work, Christiansen and Chater (1994) trained SRNs on a recursive artificial language incorporating four kinds of right-branching structures, a left-branching structure, and center-embedding. The behavior of these networks was qualitatively comparable with human performance in that the SRN predictions for right-branching structures were more accurate than on sentences of the same length involving center-embedding, and performance degraded appropriately when depth of center-embedding increased. Weckerly and Elman (1992) further corroborated these results, suggesting that semantic bias (incorporated via co-occurrence restrictions on the verbs) can facilitate network performance in center-embedded constructions similarly to the semantic facilitation effects found in human processing. Using abstract artificial languages, Christiansen and Chater (1999) show that the SRN's general pattern of performance is relatively invariant across network size and training corpus, and conclude that the human-like pattern of performance derives from intrinsic constraints inherent in the SRN architecture.

Connectionist models of recursive syntax typically use 'toy' fragments of grammar and small vocabularies. Aside from raising concerns over scaling up, this makes it difficult to provide detailed fits with empirical data. Nonetheless, some attempts have recently been made toward fitting existing data and deriving new empirical predictions from the models. For example, the Christiansen and Chater (1999) SRN model fits grammaticality ratings data from several behavioral experiments, including an account of the relative processing difficulty associated with processing center-embeddings (with the following relationship between nouns and verbs: $N_1_N_2_N_3_V_3_V_2_V_1$) versus cross-dependencies (with the following relationship between nouns and verbs: $N_1_N_2_N_3_V_1_V_2_V_3$). Human data have shown that sentences with two center-embeddings (in German) were significantly harder to process than comparable sentences with two cross-dependencies (in Dutch). Christiansen and Chater (1999) developed a measure of grammatical prediction error (GPE) that allowed network output to be mapped onto human performance data. GPE is computed for each word in a sentence and reflects the processing difficulties that a network is experiencing at a given point in a sentence. Averaging GPE across a whole sentence, Christiansen and Chater (1999) fitted human data concerning the greater perceived difficulty associated with center-embedding in German compared to cross-serial dependencies in Dutch (Bach *et al.*, 1986). The simulation results demonstrated that the SRNs exhibited the same kind of qualitative processing difficulties as humans on these two types of complex recursive constructions. MacDonald and Christiansen (2002) derived novel predictions concerning other types of recursive constructions, and these predictions were later confirmed experimentally. They mapped single-word GPE scores directly onto reading times, providing an experience-based account for human data concerning the differential processing of singly center-embedded subject and object relative clauses in human participants with different levels of reading comprehension ability.

Just as the radical connectionist approach to constituency deviates from classical constituency, the above approach to recursion deviates from the

classical notion of recursion. The radical models of recursion do not acquire true recursion because they are unable to process infinitely complex recursive constructions. However, the classic notion of recursion may be ill-suited for capturing human recursive abilities. Indeed, the psycholinguistic data suggest that people's performance may be better construed as being only quasi-recursive. The above-mentioned semantic facilitation of recursive processing further suggests that human recursive performance may be partially context-sensitive; for example, the semantically biased *The bees that the hive that the farmer built housed stung the children* is easier to comprehend than neutral *The chef that the waiter that the busboy offended appreciated admired the musicians* even though both sentences contain two center-embeddings. This dovetails with the context-sensitive notion of constituency, and suggests that context-sensitivity may be a more pervasive feature of language processing than typically assumed by symbolic approaches.

Connectionist Models of Language Processing

What is the significance of connectionist models of language processing? Will connectionism ultimately replace, complement or simply implement symbolic approaches to language? Early connectionists addressed this issue by attempting to show that connectionism could, in principle, capture aspects of language and language processing (Christiansen and Chater, 2001). These models showed that connectionist networks could in principle acquire parts of linguistic structure without extensive innate knowledge. Recent work has moved toward a connectionist psycholinguistics that captures detailed psychological data. This article has outlined several ways in which constituency and recursion – two fundamental properties of linguistic knowledge – may be accommodated within a connectionist framework, ranging from direct implementation of symbolic systems to the acquisition of constituency and recursion from untagged input. We have focused on the radical approach because this has the greatest potential impact on psycholinguistics and linguistic theory.

However, much of this research is still preliminary. Future work is required to decide whether promising, but limited, initial results can eventually be scaled up to deal with the complexities of real language input, or whether a radical connectionist approach is beset by fundamental limitations. Another challenge is to find ways – theoretically and practically – to interface models, which have been proposed at different levels of linguistic analyses, with one another (e.g., interfacing models of morphology with models of sentence processing).

Nevertheless, the connectionist models described in this article have already influenced the study of language processing. First, connectionism has helped promote a general change toward replacing box-and-arrow diagrams with explicit computational models. Second, connectionism has reinvigorated the interest in computational models of learning, by including learning properties, such as recursion and constituent structure, which were previously assumed to be present *a priori* in humans, and therefore taken for granted. Finally, connectionism tends to discard the separation between competence and performance as artificially construed, and possibly misleading. From this perspective, linguistic recursion is a conceptual artifact of the competence/performance distinction instead of a necessary characteristic of the underlying computational mechanism. In this light, the problem facing connectionist models of language processing is not whether they can implement some kind of recursive mechanism, but whether they will be able to account for the (limited) recursive structure found in natural language behavior purely in terms of nonsymbolic computation.

Connectionism has thus already had a considerable impact on the psychology of language. But the final extent of this influence depends on the degree to which practical connectionist models can be developed and extended to deal with complex aspects of language processing in a psychologically realistic way. Recent models have already started to scale up to more realistic corpora and sentence processing behaviors (Kim *et al.*, 2002; Reali *et al.*, 2003; Rohde, 2002). If realistic connectionist models of language processing can be provided, then the possibility of a radical rethinking not just of the nature of language processing, but of the structure of language itself, may be required.

Human Language Processing: Symbolic Models

S Vasishth, University of Potsdam, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

In this article we take 'symbolic models of sentence processing' to mean approaches in which processing is characterized in terms of relatively discrete, combinatorial representations. There are other properties of symbolic processing that are important for cognitive modeling more generally – for example, the ability of symbol processing to support Turing-general computation (Newell, 1990; Lewis, 2000a) – but for language processing, discrete combinatorial representations are often thought to be the hallmark of symbolic models. Defined in this manner, symbolic sentence processing models include approaches sometimes termed 'hybrid,' such as activation-based production system models, or localist connectionist models.

One important way to distinguish symbolic processing models is in terms of their ontological commitments, that is, the symbolic primitives out of which representations are composed. Arriving at an empirically and explanatorily adequate ontology of linguistic primitives is the traditional province of syntactic theory. Instead, we focus here on the variety of theoretical approaches to symbolic sentence processing that are largely orthogonal to the ontological distinctions made in syntactic theory – though often interacting with them in empirically and theoretically critical ways. We also focus here primarily on syntactic processing in comprehension, the domain of sentence processing that has received the most attention, though symbolic models exist that extend upward to discourse-level phenomena (Kintsch, 1988; Carpenter *et al.*, 1995).

The remainder of the article is organized around the following four broad approaches to symbolic sentence-processing theory, which jointly cover most existing models: (1) grammar-based approaches, which posit a tight link between competence grammars and processing phenomena; (2) symbolic complexity metrics and ambiguity resolution principles, which are abstract processing theories predicated on combinatorial syntactic representations; (3) approaches based on existing or independently motivated computational cognitive architectures; and (4) approaches based on probabilistic grammars, which appeal to frequency and experience, as encoded in a symbolic grammar formalism. Rather than surveying the entire literature, we illustrate each of the approaches by explaining the details of a few models, and provide pointers to the literature for other examples. We conclude the article with a brief section outlining points of commonality with connectionist models.

Grammar-Based Approaches

Chomsky (Chomsky, 1965) has long argued that any processing theory must include a theory of competence as a critical component, but given that a competence theory is a characterization of knowledge state that abstracts away from processing, it alone does not make processing predictions of the kind that bring it into contact with fine-grained psycholinguistic data: specific linking assumptions are required to bridge the gap. Grammar-based approaches presuppose a syntactic theory, and associate with it some fairly strong linking assumption so that the competence theory itself can be seen to drive the processing predictions.

The strongest form of this linking has been termed by Berwick and Weinberg as the type-transparency assumption. It states that "the logical organization of rules and structures incorporated in a grammar [is] mirrored rather exactly in the organization of the parsing mechanisms" (1984: 39). Many instances of this assumption can be found in the literature, and Berwick and Weinberg (1984: 39–82) provided an extensive discussion of the potential theoretical and empirical consequences of various positions.

In strong grammar-based approaches, the primitives of competence grammar are the principal explanatory force behind any observed processing difficulty. The metrics for determining processing complexity may differ as a function both of different underlying syntactic theories and of processor–grammar linking assumptions. Some theories rely on the history of the syntactic derivation and/or the number of basic operations involved (e.g., the derivational theory of complexity), while some rely on the number of rules used or violated (e.g., optimality theory).

The derivational theory of complexity (Miller and Chomsky, 1963; Fodor *et al.*, 1974) is the oldest such idea. Its central hypothesis is that the transformational model could be construed as a processing theory in addition to a competence theory (e.g., Chomsky, 1965) if "our performance on tasks requiring an appreciation of the structure of transformed sentences is some function of the nature, number and complexity of the grammatical transformations involved" (Miller and Chomsky, 1963: 481). Although early experiments showed little evidence to support such a connection between grammar and processing (e.g.,

Slobin, 1966), subsequent work has attempted to tackle the question in at least three distinct ways.

The Strong Type-Transparency Approach

One approach has been to redefine the architecture of grammar in the hopes of maintaining the strong type-transparency assumption. Examples are other versions of transformational grammar (Berwick and Weinberg, 1984; Phillips, 1990), lexical-functional grammar (Bresnan, 1978; Bresnan and Kaplan, 1982), and optimality theory (Fanselow *et al.*, 1999; Hoeks and Hendriks, 2004; Stevenson and Smolensky, forthcoming).

As an example of a sentence-processing model based on a new grammar architecture, we consider a specific approach based on optimality theory (OT) (Fanselow *et al.*, 1999). OT (Legendre *et al.*, 2000) is a grammar framework that assumes that there exists an evaluator, EVAL, and an ordered list of rules. The rules are violable, with the additional constraint – termed strict dominance – that no number of violations of a lower-ranked rule are as important as a violation of a higher-ranked one. Also provided is a function called GEN that takes as input a string (in sentence parsing, a string of words) and produces as output a set of so-called candidates. For example, given the set of words {*guess*, *we*, *saw*, *whom*} GEN would generate all the possible permutations. The candidates are simultaneously examined with respect to the ordered rules and a winning candidate declared based on the rule violations and subject to strict dominance.

This grammar architecture can be applied to sentence processing by relying on the following critical property of OT: the incremental, nonmonotonic application of the defeasible rule system allows for a ranking of contrasting sentence structures to be established, which predicts preferred parses. A simple example is the string {*guess*, *we*, *saw*, *whom*}. The two relevant rules whose relative ranking of candidates determine the outcome are antisymmetry (AS) and wh-criterion (whC); AS says that objects follow the verb, and subjects precede it, and whC that a constituent question must begin with a wh-phrase. Assuming that whC is ranked higher than AS, the winning candidate *guess whom we saw* violates only AS, whereas the permutations *guess we saw whom* and *guess we whom saw* violate the higher ranking whC constraint; and so on.

A potentially interesting property of OT is that it is considered a limiting case of a connectionist-inspired grammar formalism (Smolensky and Legendre, 2005); for example, the connectionist correlate to GEN is the start state of a network in which all possible constituents are represented as vectors, and the threshold logic units representing suboptimal candidates are deactivated, returning an optimal winner (Hale and Smolensky, 2001).

An Automata-Theoretic Approach

A second approach, championed by Joshi (Joshi, 1990; Rambow and Joshi, 1994), is to establish mathematical equivalences between grammar formalisms and computational automata, and then use processing complexity metrics naturally defined on these automata. Joshi presents complexity metrics over a (bottom-up) embedded pushdown automaton (BEPDA) to explain the difference in processing difficulty of, for example, Dutch vs. German center embedded structures (Bach *et al.*, 1986). The novel aspect of their automaton-based metric is that the BEPDA is related in a systematic way to the class of tree-adjoining grammars (TAGs), a framework for defining competence grammars (Abeillé and Rambow, 2000). The relationship is that for every TAG there is a BEPDA that accepts exactly the strings that the TAG generates, and for every BEPDA there is a TAG that generates exactly the set of strings that the BEPDA accepts. The uniqueness of this approach stems from the fact that formal models of competence and of performance are linked by the equivalence relation between the machinery; this mathematical relationship – rather than using a grammar formalism directly as a sentence-processing model – constitutes the link between grammatical representation and processing.

Grammatical Representations with an Information-Theoretical Constraint

The third type of exploration of the grammar–parser relationship is exemplified by the entropy reduction hypothesis (Hale, 2004). This model fixes a particular complexity metric (the reduction of entropy [Shannon, 1948] during incremental parsing) derived from a probabilistic grammar, and compares the effectiveness of modeling sentence-processing data with two distinct grammatical representational possibilities (Kayne's promotion analysis [Kayne, 1994] and Chomsky's adjunction analysis [Chomsky, 1977]). Although not an explicit goal of this approach, it provides a principled comparison between one set of representational assumptions vs. another in a precise manner. What makes this comparison possible is that the proposal is grammar independent and can be implemented for any grammar in the class of mildly context-sensitive grammars.

Some General Issues in Grammar-Based Models

In the grammar-based approaches, two general issues deserve comment. An assumption (either implicit or explicitly stated) in most grammar-based approaches

is that the human parser is incrementally constructing syntactic structures and, furthermore, that building syntactic structure is a prerequisite for semantic interpretation (e.g., Frazier and Clifton, 1996). But an interesting development in linguistic and psycholinguistic theory is the possible elimination of the distinction between syntactic structure building and semantic interpretation. In particular, the concurrent, incremental construction of a combined semantic and syntactic structure has emerged as an alternative position (Steedman, 2000). This has important implications for modeling real-time sentence-processing data, since considerable evidence now points to a simultaneous use of both syntactic and semantic information in constraining a parsing decision (Trueswell *et al.*, 1994).

The second issue is the relationship between various syntactic theories. Categorial grammars (Moortgat, 1997; Steedman, 2000), head-driven phrase structure grammar (Pollard and Sag, 1994), lexical-functional grammar (Bresnan, 1982), minimalism (Chomsky, 1995), tree-adjoining grammars (Abeillé and Rambow, 2000), and OT (Legendre *et al.*, 2000) are just some of the syntactic formalisms currently in existence. Significant progress has been made in exploring the connections between their very different representational assumptions (Vijay-Shankar and Weir, 1994; Frank, 2002), and these explorations raise an important issue: if one formalism *A* can be shown to be equivalent, in some well-defined sense, to some other formalism *B*, and if the ontology of *A* is argued to be associated with processing difficulty via some linking assumption to sentence parsing, then this implies that in reality the theoretical commitment of grammar-based approaches is to some common base of the equivalent frameworks rather to the specific primitives of a particular one. An important step in grammar-based approaches is thus identifying exactly what this common theoretical commitment is – what must be invariant about the grammar to derive the same empirical predictions. For example, is there an empirical motivation for characterizing dislocations such as wh-movement as movement rather than some kind of feature sharing? There have been attempts to distinguish between positing movement-based traces and lexical association accounts (Gibson and Hickok, 1993; Nakano *et al.*, 2000), but much more work remains to be done in this area.

Symbolic Models Involving Complexity Metrics and Ambiguity Resolution Principles

A second kind of model proposes complexity metrics or ambiguity resolution principles predicated on symbolic syntactic structures. The metrics and ambiguity principles can be defined without reference to a particular architecture for the competence grammar, though particular syntactic representations must be assumed in order to make specific predictions. The common underlying assumption of these models is that the metrics or principles are abstract characterizations of the resource-boundedness of human working memory for linguistic processing.

Ambiguity Resolution Principles

The best-known theory of this type is minimal attachment (Frazier, 1979). Minimal attachment is assumed to be a principle that accounts for attachment preferences in ambiguous sentences. Sentences such as *The girl saw the boy with the telescope* are ambiguous because, in the absence of a context, we do not know whether the prepositional phrase *with the telescope* modifies the verb *saw* or the noun *boy*. Minimal attachment provides a simple formal statement of which attachment should be preferred: it is the attachment that yields the simplest structure, where 'simplest' can be defined as the structure that introduces the fewest new syntactic nodes. Thus, minimal attachment depends crucially on the representational assumptions in some syntactic theory. For example, in the prepositional phrase attachment example, the minimal attachment prediction depends on the precise syntactic structure assigned to the VP-adjunct vs. NP-adjunct. Frazier (1979) assumed that the NP-adjunction introduces an additional syntactic node, predicting initial VP attachment in an NP-VP-PP ambiguity.

Another issue involving ambiguity is early vs. late closure (Frazier, 1979). The relevant phenomena can be illustrated in the following way. In a sentence such as *After the student moved the chair broke*, a prosodic break after *moved* (or a comma if the sentence is in written form) will 'close' the phrase *After the student moved* early; this is called early closure, and is the intended utterance. By contrast, if the sentence is spoken (or written) without a prosodic break (or comma) after *moved*, the perceiver tends to 'close' the phrase late, at the end of *the chair*, in this case incorrectly. This initial misanalysis is called late closure. In the absence of any prosodic information (and without any punctuation), such sentences often cause garden-pathing (initial misanalysis due to ambiguity).

Frazier proposed these principles with the specific idea of a constrained-capacity working memory system. Regarding late closure, Frazier (1979: 39) said, "It is a well-attested fact about human memory that the more structured the material to be remembered, the less burden the material will place on immediate memory. Hence, by allowing incoming material to be

structured immediately, Late Closure has the effect of reducing the parser's memory load." Similarly, regarding minimal attachment (1979: 40): "The Minimal Attachment strategy not only guarantees minimal structure to be held in memory, but also minimizes rule accessing. Hence, [minimal attachment is also an 'economical' strategy] in the sense that [it reduces] the computation and memory load of the parser." Thus, the limited capacity of working memory was a central motivating factor in the development of theories of ambiguity in sentence processing.

Going beyond the purely capacity-based explanation for ambiguity is Frazier and Clifton's theory of construal (Frazier and Clifton, 1996). One of the goals of this theory is to account for attachment ambiguities like *The girl with the hat that looked funny*. . . . Here, it is unclear who was funny, the girl or the hat. Construal predicts a preference for lower attachment (modification of *hat* rather than *girl)* as follows. Two kinds of relation are assumed, primary and secondary. Primary relations are, for example, those between verbs and their arguments, while secondary relations are relations between modifiers and the element modified, such as the modifying relative clause *that was funny* and the modifiable elements *girl* and *hat*. Frazier and Clifton proposed a construal principle, which (in a simplified form) states that if a nonprimary relation needs to be attached in a syntactic structure, this nonprimary relation must be associated with the phrase containing the most recent theta assigner. This last theta assigner is *with* and the phrase it occurs in is *with the hat*. This accounts for the low attachment preference.

General Structural Complexity Metrics

The theories discussed above focus on ambiguity resolution. Although ambiguity is an extremely important problem for efficient parsing, another important issue is the complexity of globally unambiguous sentences. Several theories attempt to address this issue. The most prominent ones are dependency locality theory (Gibson, 1998, 2000), and early immediate constituents (Hawkins, 1994, 1998, 2001); we describe the first one briefly.

Dependency locality theory (DLT) aims to account for processing difficulty in both ambiguous (garden path) structures and unambiguous ones, such as center embeddings. DLT assumes that during the course of sentence parsing, computational resources in working memory are needed for two aspects: storage of the structure built up thus far and integration of the current word into the structure built up thus far. Based on these two components, a cost metric is defined which predicts relative processing difficulty. There is a storage cost, measured in memory units (MUs), and an integration cost, measured in energy units (EUs).

Input words:	The	reporter	disliked	the	boy
Heads needed:	Noun, Verb	Verb	NP	Noun	–
Storage cost (MUs):	2	1	1	1	0

Figure 1 Illustration of DLT's storage cost computation.

Storage cost is computed as follows: 1 MU is associated with each syntactic head required to complete the current input as a grammatical sentence. For example, as shown in Figure 1, for the first word, *The*, a noun and a verb are needed to complete the sentence grammatically, so the storage cost is 2 MUs. At the second word, *reporter*, only a verb is needed, so the storage cost is 1 MU. For the next word, *disliked*, one NP is needed, so the cost is 1 MU. The cost for the next word, *the*, is also 1 MU, since only a noun is needed to complete the input string as a grammatical sentence. The last word incurs no cost since it can complete the sentence.

The cost of integrating a current word *A* with an existing structure *S* depends on locality, i.e., the distance between them. The processing cost depends on the complexity of the computations that took place between *A* and *S* and is assumed to be linearly related to the number of discourse referents (DRs) introduced between the two items. A DR is assumed to be "an entity that has a spatiotemporal location so that it can later be referred to with an anaphoric expression, such as a pronoun for NPs, or tense on a verb for events" (Gibson, 2000: 103).

Apart from storage cost and integration cost, the other factors that are assumed to affect comprehension difficulty are:

1. The frequency of the lexical item being integrated: the lower the frequency, the greater the processing difficulty.
2. The contextual plausibility of the resulting structure: the less plausible the final structure, the greater the processing difficulty.
3. The discourse complexity of the final structure: nonfocused entities and elements introduced using definite descriptions are less accessible (and are therefore harder to process) than focused entities. Least accessible of all are elements introduced using indefinite NPs: "Elements new to the discourse, which are usually introduced using indefinite NPs, require the most resources because they must be constructed in the discourse model . . . it is assumed that processing the head noun of an NP that refers to a new discourse object consumes substantial resources, and processing the head verb of a VP that refers to a new discourse event (also a discourse referent) consumes substantial

resources, but processing other words does not consume substantial resources in the discourse processing component of structure building" (Gibson, 2000: 103). Also see Warren (2001: 33–44).

4. If the current word is not compatible with the highest ranked structure built so far, there is reanalysis difficulty.

The storage and integration costs together provide a measure of integration time, which gives the complexity at any given point, as well the as overall complexity, of a sentence. Gibson assumed the following regarding these two costs: (i) integrations and storage access the same pool of resources; (ii) resources have fixed capacity; (iii) each predicted syntactic head takes up a fixed quantity of resources; and (iv) the overall acceptability of a sentence depends on the maximal integration time complexity experienced during the parsing process.

In sum, sentence processing according to the DLT is constrained by limited resources in working memory. This limit on resources is quantified in terms of integration and storage costs of linguistic elements as they are processed in real time.

Cognitive Architectures and Sentence Processing

Another approach to sentence-processing theory is to apply independently motivated theories and principles from cognitive psychology research. One instance of such an approach takes as its starting point a fixed cognitive architecture. These theories derive processing explanations from general cognitive processing principles such as activation decay and memory interference.

Activation-Based Architectures

Activation models have dominated the cognitive-architecture-based approaches. In activation-based models, symbolic long- and/or short-term memory elements have a continuous quantity (activation) associated with them that affects processing in some way. Early examples include the Just and Carpenter READER model, which was based on a production system architecture developed concomitantly with the sentence-processing model (Just and Carpenter, 1987). The READER model later evolved into a model of individual differences in language comprehension, with a quantitative parameter (amount of available activation) used to model differences in working memory capacity (Just and Carpenter, 1992). Several other sentence-processing models have been developed in general activation-based architectures developed jointly with a specific language model (Kintsch, 1988; Stevenson, 1994; Vosse and Kempen, 2000; Tabor and Hutchins, 2004; Tabor *et al.*, 2004).

Independent Cognitive Architectures

More recently, there have been attempts to derive sentence-processing models from independent cognitive architectures developed largely outside the domain of linguistic processing. Examples are the SOAR-based architecture in Lewis (1993) and the authors' ACT-R-based sentence-processing model (Lewis and Vasishth, forthcoming). As an example of this approach, and the cognitive architecture approach more generally, we briefly discuss our own model.

Brief Overview of ACT-R

The cognitive theory ACT-R (Anderson *et al.*, 2004) is implemented as a general computational model and incorporates constraints developed through considerable experimental research on human information processing. The ACT-R theory relevant for the present discussion and the parsing model are outlined next, and its empirical coverage is briefly discussed.

In its essence, ACT-R consists of two distinct systems, declarative memory and procedural memory. Declarative memory consists of items (chunks) identified by a single symbol. Each chunk is a set of feature/value pairs; the value of a feature may be a primitive symbol or the identifier of another chunk, in which case the feature/value pair represents a relation.

In addition to the memory systems, focused buffers hold single chunks. There is an architecturally fixed set of buffers, each of which holds a single chunk in a distinguished state that makes it available for processing. Items outside of the buffers must be retrieved to be processed. The three important cognitive buffers are a goal buffer, a problem state buffer, and a retrieval buffer. The goal buffer serves to represent current control state information, and the problem state buffer represents the current problem state. The retrieval buffer serves as the interface to declarative memory, holding the single chunk from the last retrieval. This structure has much in common with conceptions of working memory and short-term memory that posit an extremely limited focus of attention of one to three items, with retrieval processes required to bring items into the focus for processing (Wickelgren *et al.*, 1980; McElree and Dosher, 1993).

All procedural knowledge is represented as production rules (Newell, 1973) – asymmetric associations specifying conditions and actions. Conditions are patterns to match against buffer contents, and actions are taken on buffer contents. All behavior arises from production rule firing; the order of behavior is not fixed in advance but emerges in response to the dynamically changing contents of the buffers.

The sentence-processing model critically depends on the built-in constraints on activation fluctuation of chunks as a function of usage and delay. Chunks have numeric activation values that fluctuate over time; activation reflects usage history and time-based decay. The activation affects a chunk's probability and latency of retrieval.

ACT-R also assumes that associative retrieval is subject to interference. Chunks are retrieved by a content-addressed (McElree, 2000), associative retrieval process. Similarity-based retrieval interference arises as a function of retrieval cue overlap: the effectiveness of a cue is reduced as the number of items associated with the cue increases. Associative retrieval interference arises because the strength of association from a cue is reduced as a function of the number of items associated with the cue.

A Sentence-Processing Model Based on ACT-R

The sentence-processing model consists of a definition of lexical items in permanent memory defined in terms of feature/value pairs, and a set of production rules specifying a left-corner parser (Aho and Ullman, 1977) . The most important property of a left-corner parser in this context is that structure is built as input comes in; there is no waiting period (lookahead; cf. Marcus, 1980) before any parsing decisions are made. The motivation for such an incremental parsing model comes from previous work in the literature (see, for example, Tyler and Marslen-Wilson, 1977; Johnson-Laird, 1983; Scheepers *et al.*, 1999).

The model has been applied to five different published reading experiments (from three laboratories and two different paradigms). The simulations provide detailed accounts of the effects of length and structural interference on both unambiguous and garden path structures. The phenomena covered include an interesting novel prediction of the model, viz., a crossover interaction of the effect of length and structural interference on reanalysis cost vs. initial attachment cost: interference affects attachment more than reanalysis, while the reverse is true for length. The reason for this interaction is that the dispreferred structure does not receive additional activation boosts from participating in the ongoing parse, and so length disproportionately affects its retrieval during garden path reanalysis. This retrieval does not, however, incur greater interference cost, because that cost is determined by the intervening structures, which are often the same regardless of which interpretation was pursued. Van Dyke and Lewis (2003) obtained quantitative estimates of these effects and their interaction, using ambiguous and unambiguous versions of the constructions in (1). The model provides accounts of reading times in the critical disambiguating region and the ambiguous region (the latter testing predictions of load effects).

(1a) [short] The assistant forgot (that) the student was standing in the hallway.
(1b) [long/simple] The assistant forgot (that) the student who was waiting for the exam was standing in the hallway.
(1c) [long/complex] The assistant forgot (that) the student who knew that the exam was important was standing in the hallway.

An important result in this model is that all fits were obtained with one free scaling parameter that was fixed across all the simulations; all remaining quantitative parameters were set to default values from the ACT-R literature. The remaining theoretical degrees of freedom in the model are the production rules that embody the parsing skill, and these rules represent a straightforward realization of left-corner parsing conforming to one overriding principle: compute the parse as quickly as possible. This approach thereby considerably reduces theoretical degrees of freedom – both the specific nature of the strategic parsing skill and the mathematical details of the memory retrieval derive from existing theory, plus the assumption of fast, incremental parsing.

In summary, this sentence-processing model (a) provides an integrated, quantitative account of both length and structural complexity effects in both ambiguous and unambiguous constructions; (b) predicts reading times in both ambiguous and disambiguating regions; (c) probabilistically predicts both parsing failures and reading times; and (d) provides single-parameter quantitative predictions across multiple experiments and paradigms.

Probabilistic Models

In probabilistic models, the starting point is a set of symbolic rules that generate syntactic structures (an example is a context-free grammar specification). To such rules a probability is assigned in the following way: the probability of a rule's left-hand side expanding to the right-hand side is assigned a numerical value between 0 and 1, this number being the product of the probabilities of the right-hand side nonterminal symbols. All rules with the same left-hand side have a total probability summing to one, and a parse tree's probability is a product of the set of all rules used to generate the tree (Manning and Schütze, 1999).

Ambiguity Resolution Using a Probabilistic Approach

Probabilistic models capture an important aspect of sentence processing: the role of experience and frequency in language processing. They also furnish

good models of parsing preferences, of ambiguity resolution, and of gradedness in acceptability (Crocker and Keller, forthcoming).

We present next an instance of a probabilistic approach and show how it applies to a well-known ambiguity resolution issue (Jurafsky, 1996). This model takes as its starting point a syntactic formalism known as construction grammar. Construction grammar assumes that complex, nonlocal constructions are stored along with lexical entries in the mental grammar. Jurafsky's model assigns probabilities to each such construction, and these probabilities determine the likelihood of their being accessed. The probabilities, which are analogous to initial activation values of entities in the mental grammar, are assigned using a corpus (the Penn Treebank) to compute maximum likelihood estimates from relative frequencies. In addition, valency frequencies of verbs are taken from Connine *et al.* (1984).

The classic garden path sentence, *the horse raced past the barn fell*, is then explained as follows. Of the two possible interpretations, one has *raced* as an intransitive verb (main verb interpretation) and the other has *raced* as a transitive (reduced relative interpretation). The intransitive valence has a probability of 0.92, while the transitive one has a probability of 0.08. In addition the reduced relative interpretation requires a context-free grammar (CFG) rule to be applied as in (2):

(2) NP → NP XP

This rule's probability (computed from the Penn Treebank) is 0.14. The combination of the transitive verb valency probability and the CFG rule is $0.14 \times 0.08 = 0.0112$. Since this combined probability of the reduced relative interpretation is $0.92 \div 0.0112 = 82.14286$ times lower than that of the preferred interpretation, it is pruned away during processing because of an assumed beam search mechanism that rejects any parses that are too far away from the best.

Some Open Issues in Probabilistic Models

Two important issues in sentence processing that remain to be addressed in detail are: explaining moment-by-moment fluctuations in processing difficulty, and the relative difficulty of complex yet unambiguous sentences. The ability to explain reading time data gathered by methods like self-paced reading and eyetracking requires further refinement of probabilistic models, which generally provide a single real number for the full sentence parse, which serves as a measure of processing difficulty. The second issue is that current probabilistic models do not have as broad an account as some other approaches (Gibson, 2000; Hawkins, 2001; Lewis and Vasishth, forthcoming) of globally unambiguous sentences, such as subject vs. object relative clause processing, center embedding phenomena, etc. Some progress has been made in this direction (Crocker and Brants, 2000; Hale, 2001; Korthals, 2001; Narayanan and Jurafsky, 2002, Jurafsky, 2003; Vasishth and Uszkoreit, 2004), but much more remains to be done.

Symbolic Processing Models and Their Relation to Connectionist Models

We conclude by briefly considering symbolic models in terms of several properties normally associated with connectionist models: parallel processing, interactivity (simultaneous application of multiple constraints), and the graded, continuous nature of human performance.

First, it should be clear that parallel vs. serial processing is a distinction that is orthogonal to symbolic vs. nonsymbolic processing. For example, all of the prominent symbolic cognitive architectures (Soar [Newell, 1990], EPIC [Kieras and Meyer, 1997], and ACT-R [Anderson *et al.*, 2004]) include substantial amounts of parallelism. In the domain of sentence processing, most symbolic models also assume parallel processes – for example, the ACT-R-based model above assumes that memory retrieval happens in parallel with other cognitive and perceptual processes.

It is also worth clarifying here a potential source of confusion in the sentence processing literature that relates to the serial vs. parallel processing issue (Lewis, 2000b). A distinction is often made between serial and parallel parsing, but these terms are generally meant to refer to depth-first search vs. breadth-first search methods, respectively – that is, serial parsing pursues a single interpretation while parallel parsing pursues multiple interpretations. But this distinction is also orthogonal to serial vs. parallel processing as it is used elsewhere in the connectionist and symbolic modeling literature, where it simply refers to the temporal sequentiality or overlap of processes. Thus, one can have a serial-processing parallel parser, or a parallel-processing serial parser. In fact, the ACT-R model described above is an example of the latter.

Second (and related to parallel processing), simultaneous constraint interaction and constraint satisfaction from different sources (e.g., the immediate effect of context on parsing) is also completely consistent with symbolic processing. One example is the modular symbolic architecture sketched in Altmann and Steedman (1988), which involves multiple constraint satisfaction from different sources.

Finally, although we defined symbolic-processing systems as ones that manipulate relatively discrete combinatorial representations, such systems are still

capable of accounting for aspects of the continuous, graded nature of human performance. Examples are the probabilistic approaches in Hale (2004) and Crocker and Keller (forthcoming), optimality theoretic approaches, and the ACT-R model mentioned in this article (Lewis and Vasishth, forthcoming).

Looking ahead, it seems clear that labels such as 'symbolic' and 'connectionist' will continue to be at best vaguely descriptive categories, and sharper theoretical discussion will appeal to precisely articulated issues such as the nature of the parsing search strategy, the precise relationship of parallel processes in terms of memory and control, the distribution of linguistic knowledge across the architectural components, the nature of codified experience, and the interaction of language-specific and more general cognitive resources. The current class of symbolic cognitive models comprises a rich body of theory from which to pursue these and other pressing research questions.

Human Language Technology

G Hirst, University of Toronto, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

Human language technology, or *technologies*, or *HLT*, is the name given collectively to the various areas of technology, especially computer technology, that involve applications to tasks in which language is central. Traditionally, three subfields have been recognized: speech technology, information or document retrieval, and natural language processing. Each is described in detail in a separate article in this encyclopedia, as are many of the specific topics of research and areas of application within each subfield. The use of the name *human language technology*, however, is usually intended to emphasize the unity of the field, the integration of elements from different subfields, and an emphasis on application rather than theory. For example, all three subfields would be involved in creating a system that took as its input video or audio recordings of news broadcasts, and automatically transcribed the soundtrack (using speech recognition) to create a written summary of the broadcast (using methods from natural language processing) and to retrieve segments of the video or audio in response to topical requests from a user (using methods from information retrieval).

The three subfields arose as distinct enterprises in separate disciplines with differing research methods and traditions – natural language processing in computer science, speech technology in electrical engineering and digital signal processing, and document and information retrieval in library science – and they have only recently been seen as together forming an integrated area of research with significant interests in common. Early moves in this direction were initiated by U.S. agencies that funded research in the subfields: the first Human Language Technology Conference was held in 1993 with the aim of bringing agency-funded researchers together to learn one another's methods, goals, and interests. In 2001, the conferences became an annual event and were opened to the general international research community; in 2003, their organization was turned over to the Association for Computational Linguistics (*see* **Association for Computational Linguistics**).

A related term, often used in Europe particularly since the early 1990s, is *language engineering* or *natural language engineering* (the latter being also the name of a research journal). While perhaps in practice natural language engineering is more centered on textual applications than on speech, this term, too, implies an orientation toward applications involving language with less regard for the discipline or subfield in which the work arises. Both terms are now commonly used in Europe.

Human Reasoning and Language Interpretation

K Stenning, Edinburgh University, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

Psychologists concerned with deductive reasoning have developed a number of laboratory tasks, bodies of experimental data, and theoretical frameworks concerned with what undergraduate subjects do when presented with what are intended as the premises of classical deductive arguments (for a review, see Evans *et al.*, 1993). The linguistic materials used in these tasks often originate in logic textbooks, and the criteria of correctness used in assessing subjects' performance also originate in classical logic. The experimental subject is generally presented with these materials out of all context other than the injunction to 'say what follows' from the premises. The premises are like messages washed up in a bottle on the laboratory beach. Viewed from a suitable perspective, some of the data from these tasks may yet be extremely interesting as communications *in vacuo* and be made to speak to theories about communication under more normal pressures.

For example, when subjects are given the premises *If she has an essay, she's in the library* and *She has an essay,* then an overwhelming majority of them endorse the conclusion *She's in the library.* However, given the additional premise *If the library is open, then she's in the library,* about half of them withdraw the previous conclusion (Byrne, 1989). Subjects thus reason non-monotonically – an additional premise destroys the perceived validity of an earlier conclusion. Classical logic is always monotonic – adding premises never invalidates conclusions.

For another example, about 20% of undergraduate students given the premise *All A are B* and asked whether it then follows that *All B are A*, famously accept this as a valid conclusion. This pattern of reasoning is so well known among logic teachers that it was long ago dubbed the 'fallacy of illicit conversion.' Less well known is the fact that about 20% of undergraduate students given the premise *Some A are B* and asked whether it then follows that *Some B are A* refuse to accept this as a valid conclusion. Even more interestingly, these two 20% groups of subjects are disjoint. Subjects who commit the famous fallacy do not commit the less-illustrious error and vice versa (Stenning, 2002: Ch. 5; Stenning and Cox, in press). Again, the classification of correct reasoning and error are derived from classical logic in which the concept of validity stipulates that a valid conclusion must be true in all models of the premises.

By way of a last example, subjects can be given four cards with letters on one side and numbers on the other, a conditional rule to the effect that *If there's a vowel on one side then there's an even number on the other*, and the instruction to choose all and only the cards that they need to turn in order to test the truth value of the rule. Such undergraduate subjects overwhelmingly fail to turn over the vowel and the odd number that classical logic dictates they should. Most turn the vowel and the even number (Wason, 1968).

This last experimental observation provoked a search for materials that would make this reasoning as simple as the task appears, and this search eventually yielded the following observation. The rule was changed to a familiar drinking-age law: *If you drink alcohol, you must be over 18 years of age* and the cards described drinkers' ages and their drinks (16/20; whiskey/orange), and the subjects were asked to choose the cards they needed to turn to find out who, if anyone, was breaking the law. The vast majority turned the whiskey and the 16 card, just as classical logic dictates.

This observation gave rise to a widespread rejection of logic as a basis for a theory of human reasoning, the argument being that changing the content changes the reasoning, and logic stipulates that reasoning always proceeds *purely in virtue of form*, so logic is for the birds – or at least not for humans. This argument has provided inspiration to a number of influential theories of human reasoning: mental models theory (Johnson-Laird and Byrne, 1991), evolutionary psychology (Cosmides and Tooby, 1992), relevance theory (Sperber and Wilson, 1995), and dual-process theory (Evans, 2003).

All these observations of striking reasoning phenomena share the simplicity of the sentences involved. Simple conditional sentences or simple monadic quantifications might appear to be stony ground on which to develop rich theories of human interpretation. However, the present argument is that these materials can provide strong motivation for taking seriously, and at face value, some of the contributions of modern logic to the theory of interpretation. A theory of interpretation that can encompass these materials and situations has to regard interpretation as a process that assigns logical forms to sentences only in their communication setting – embedded in their tasks and contexts. Far from a translation process from sentences of English into logical sentences, the process of assigning logical form becomes one of setting a host of parameters affecting the nature of validity, the syntax and semantics of the language, the number and identity of truth values, and many other features. These parameters are set in virtue of what is

being done with the sentence – the participants' goals and understanding of each others' intentions – as much as by inspecting words in sentences.

To cut a long story short and bring an abstract logical treatment down to a concrete analysis of these examples, the drinking-age law is known from its content to have deontic force. As a consequence, assessing whether cases violate the law does not involve testing the truth value of the sentence, and the task is trivially easy. The vowels and consonants rule is likely, *in vacuo*, to be interpreted as a description, and this likelihood is reinforced by the instruction to assess its truth value. The truth conditions of conditional sentences occupy substantial shelf space in the philosophy of logic literature. On a lawlike interpretation of the conditional robust to exceptions, no amount of card turning will determine the truth of the rule, and so the subjects' logically correct response (on this logic) would be to reject the task as impossible. There is evidence of just such inclinations (Stenning and van Lambalgen, 2004).

This common lawlike robust interpretation of the conditional also arguably underlies the nonmonotonic reasoning in the first example of our diligent student's whereabouts. The task here is likely to be interpreted by the subject as to credulously interpret the premises in the experimenter's materials. Encountering the second conditional, *if the library is open then she's in the library*, with this mind-set is likely to result in its being interpreted as a repair to the first too-general statement – a nonmonotonic process that changes the interpretation of the first conditional so that the original conclusion is no longer valid in any logic. The credulous logic involved in this interpretation is different in its syntax, semantics, number of truth values, and concept of validity from the material implication of classical logic. Here the conditional is not a connective so much as a noniterable license-for-inference; its semantics are given by a three-valued interpretation in which the concept of validity is not the classical concept of the conclusion's truth in all models of the premises but rather its truth in *preferred* models on a certain technical definition of preference.

If many subjects can reasonably be expected to adopt a credulous attitude to the interpretation of experimenters' messages from the bottle on the laboratory beach, then this may also explain the patterns of fallacy and omission of valid conclusions in the quantified examples. *In vacuo*, our credulous construction of a model for the premise *All A are B* will have some As in it that are Bs, and when we are asked whether all the Bs in that model are As then, operating by what is called closed-world reasoning, the correct answer would be yes. So subjects with this strongly credulous preferred-model-construction understanding of the experimenter's intentions will commit what would be a fallacy of classical logic, if classical logical inference were what they were trying to do. A subject with a somewhat different, but still nonclassical, understanding of the experimenter's intentions might observe that the conditions under which a speaker would assert *Some A are B* are distinctively different from the conditions under which they would assert *Some B are A* – the same information is packaged for different audiences – and this might be sufficient to lead them, not unreasonably, to reject the idea that the one follows from the other. 'Following from' is, after all, a highly elastic concept in English. An approach along these lines invests in a theory of the many interpretational stances subjects may take. It stands some hope of explaining why the 20% of subjects who commit the fallacy don't fail to draw the conclusion and *vice versa*: having one model of the communication makes it unlikely that one holds other incompatible models simultaneously.

Logic has always been a game of two halves – interpretation and derivation – and modern logic is a representational supermarket of distinct systems for modeling the highly heterogeneous things that people can do in communicating. Logical reasoning (derivation) proceeds purely in virtue of form once an interpretation has been assigned, but the process of assigning an interpretation is as content-involved as it is possible to be. If derivation yields some unexpected result, reinterpretation is often the order of the day, so these processes are interleaved in real communication. Modern logic is a highly articulated framework for explaining why and how reasoning is so exquisitely sensitive to task, context, and content – possibly useful to birds but certainly essential to understanding human reasoning.

It is instructive to compare this logical approach to interpretation with Gricean programs of research, which assume the uniqueness of classical logic as an interpretation, but augment it by pragmatic principles such as Grice's maxims of quantity – "say as much as is needed but no more!" A number of psychologists have appealed to such programs to bridge the observed gaps between classical logic and their observations (Politzer, 2004; Roberts *et al.*, 2001). The two programs have much ground in common. For example, the closed-world reasoning that makes illicit conversion valid may be reconstructable in Gricean terms. Helpful speakers provide all and only relevant information and expect us to draw these implicatures. Taking the multiplicity of logics seriously and assuming that logical form is a function of much more than the sentences that appear opens up research to the rigors of formulating logical systems that model the

data. The Gricean (and related) programs have always been notoriously hard to compute. From a cognitive point of view, the logical approaches have opened up the issue of how the systems can be implemented in the mind. The default logic appealed to here turns out to be highly tractable and implementable in spreading activation networks (Stenning and van Lambalgen, in press). The next few years should determine which is the more productive program of research for semantics and pragmatics.

Assessment of peoples' reasoning requires a firm foundation on the interpretations they adopt. This does not mean that their reasoning will be perfect, or that they cannot be faulted for adopting inappropriate interpretations. The rich framework for interpretation provided by modern logic offers the apparatus to link formal studies with a much wider range of communication, both *in vacuo* and in context.

Humboldt was born in Potsdam into a family of Prussian nobility. (His full name was Friedrich Wilhelm Christian Karl Ferdinand Freiherr von Humboldt. Alexander von Humboldt [1769–1859], the famous natural scientist and explorer, was his younger brother.) After studying law at the universities of Frankfurt an der Oder and Göttingen in 1787–1789, Humboldt alternately traveled in Europe, worked as a jurist in civil service, and lived the life of an independent scholar (especially since his marriage into a wealthy family in 1791) for several years. From 1794 to 1797 he lived in Jena with his family, where he became close friends with Schiller and Goethe, and then in Paris from 1797 to 1801, where he met the 'Idéologues,' who advocated a materialist philosophy which had considerable influence on its time. From Paris he occasionally traveled to Spain. There he learned about the Basque language, which he began to study extensively in relation to the history and culture of the region and its people. From 1802 to 1808 Humboldt was Prussian ambassador to the Vatican in Rome, where he expanded his already vast knowledge of antiquity and the classical languages. Back in Germany he was appointed councillor of state, reformed the educational system, and founded the University of Berlin. From 1810 to 1818 Humboldt served as a diplomat in various European capitals and at several important conferences, and in 1819 he eventually became Prussian minister ('Minister für ständische und kommunale

data. The Gricean (and related) programs have always been notoriously hard to compute. Humboldt, Wilhelm von (1767–1835)

K Willems, University of Ghent, Ghent, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Humboldt was born in Potsdam into a family of Prussian nobility. (His full name was Friedrich Wilhelm Christian Karl Ferdinand Freiherr von Humboldt. Alexander von Humboldt [1769–1859], the famous natural scientist and explorer, was his younger brother.) After studying law at the universities of Frankfurt an der Oder and Göttingen in 1787–1789, Humboldt alternately traveled in Europe, worked as a jurist in civil service, and lived the life of an independent scholar (especially since his marriage into a wealthy family in 1791) for several years. From 1794 to 1797 he lived in Jena with his family, where he became close friends with Schiller and Goethe, and then in Paris from 1797 to 1801, where he met the 'Idéologues,' who advocated a materialist philosophy which had considerable influence on its time. From Paris he occasionally traveled to Spain. There he learned about the Basque language, which he began to study extensively in relation to the history and culture of the region and its people. From 1802 to 1808 Humboldt was Prussian ambassador to the Vatican in Rome, where he expanded his already vast knowledge of antiquity and the classical languages. Back in Germany he was appointed councillor of state, reformed the educational system, and founded the University of Berlin. From 1810 to 1818 Humboldt served as a diplomat in various European capitals and at several important conferences, and in 1819 he eventually became Prussian minister ('Minister für ständische und kommunale

Angelegenheiten'). He retired from civil service on Dec. 31, 1819 (in the wake of the Carlsbad Decrees which imposed censorship on the press, supervision of universities and student organizations etc.), devoting most of his time to linguistic research and regularly presenting linguistic papers at the Berlin Academy. He studied several languages, including Sanskrit, native languages of America, partly from material his brother had acquired on his journeys (e.g., the native Aztec language in Mexico) and Malayo-Polynesian languages (e.g., Kawi). He introduced Champollion's discoveries on the Egyptian hieroglyphs to the German public. The work of the French sinologist J. P. Abel Rémusat led him to study Chinese as well. Humboldt died at his exquisite manor in Tegel (now in Berlin) in 1835.

Humboldt's versatility is legendary. He was an influential politician who combined his civil duties with sustained reflection on public matters, to which several writings, especially on the state and educational reforms, bear witness. He was also an art collector, writer, and translator (his translation of Aeschylus's *Agamemnon* is well known), but above all he was a humanist with a great talent for languages. As a young man he already took a keen interest in philosophical, philological, literary, and aesthetic issues and was considerably influenced by G. W. Leibniz, I. Kant, Schiller, and Goethe. Humboldt's writings on language, most of which appeared posthumously (the 17 volumes of his collective writings, *Gesammelte Schriften*, appeared in Berlin between 1903 and 1936; all citations in this article refer to this edition), are the product of research spread over several decades. They contain many discoveries and a host of subtle structural descriptions, bearing testimony to the author's consummate skill as a linguist, philosopher of language, and cultural anthropologist.

For Humboldt the study of language was part and parcel of a vast anthropological project, through which he ultimately tried to implement his conservative educational ideals. One of the most remarkable features of Humboldt's writings on language from a modern point of view is that they are always contributions to empirical linguistics and to the philosophy of language (including ideological assessments) at the same time. They are conceived as a synthesis of ideational insights into language in general on the one hand and minute observations based on empirical linguistic data on the other. Informed by a profound knowledge of many, often very different, languages, Humboldt was able to reconsider, from the vantage point of language, the philosophical issues of his time, especially those engendered by Kant's so-called transcendental philosophy, including the nature of thecategories of human understanding, reason, imagination, and morality. Unlike Herder, who attempted in vain to rewrite Kant's *Critique of pure reason* mainly by replacing reason with language (*Verstand und Erfahrung/Vernunft und Sprache. Eine Metakritik zur Kritik der reinen Vernunft*, 1781; cf. *see* **Herder, Johann Gottfried (1744–1803)**), Humboldt did not object to the central claims about reason and understanding that Kant had put forward in his three *Critiques*. On the contrary, Humboldt's own research can be read as an endeavor to adapt Kantian philosophy to the theory of language. At the same time, however, he succeeded in preserving the true assets of Herderian romanticism, which was directed against the rationalist logicistic tradition of the *Allgemeine Sprachlehre* ('Universal Grammar') in the 18th century, and combined the view that the study of language is the clue to understanding the spiritual and intellectual condition of mankind with the historically very important insight that the diversity of languages constitutes a universal aspect of language (Humboldt, 1903–1936: VI, 4–6). Not surprisingly, the collocation 'die Verschiedenheit des menschlichen Sprachbaues' ('the diversity of human language structure') enters into the title of Humboldt's two main texts on language (written 1827–1829 and 1830–1835). For Humboldt, language, nationhood, and the intellectual activity of the individual are indissolubly interconnected and can be separated only by an act of abstraction, which, although necessary, is legitimate within the purview of scientific research only (Humboldt, 1903–1936: VI, 119–128, 197, 241–245; VII, 46). Furthermore, language is, strictly speaking, comparable to nothing else (Humboldt, 1903–1936: IV, 16).

Humboldt believed that universal concepts and forms of understanding unique to the human species come to be realized in historical and culturally bound instantiations, and it is in these particularizations of the universal that natural language assumes a central role. A language is not merely a code based on conventions and used for communication. Humboldt even went so far as to reject the view that language is conventional altogether: according to him, such a view erroneously presupposes a shared conceptual world of objects prior to language (Humboldt, 1903–1936: III, 167; cf. VI, 119, 155). In the same vein, defining language as a tool for communication is bound to lead to mistakes (Humboldt, 1903–1936: VII, 20) because it is based on an external and arbitrary point of view. For Humboldt language is much more; it is the locus *par excellence* where the principles of human understanding and knowledge as well as the diversity of mankind meet. Language is the organ that shapes thought (Humboldt, 1903–1936: 'Die Sprache ist das bildende Organ des Gedanken,'

VI, 152, and VII, 53). At the same time, Humboldt was convinced that a rich inflectional system with complex grammatical forms was particularly beneficial for abstract (philosophical and formal) reasoning (Humboldt, 1903–1936: IV, 285–313).

Moreover, in every language there is a proper world view ("so liegt in jeder Sprache eine eigenthümliche *Weltansicht*," Humboldt, 1903–1936: VI, 180; cf. IV, 33, 420). This stance generally – but somewhat misleadingly – goes under the name of 'linguistic relativism' in linguistic historiography. Although it has had a profound and enduring influence on the later history of linguistics (*see* **Boas, Franz (1858–1942); Sapir, Edward (1884–1939); Coseriu, Eugenio (1921–2002)**), its reception rarely does full justice to the complexity and breadth of Humboldt's original thought, in which it is not some kind of challenging hypothesis but a corollary of a general idealistic focus on language. For Humboldt, linguistic worldviews are the natural result of the potentially infinite ways in which the universal language competence in man moulds the substance of experience. Furthermore, the rules and forms of meaning from which each language derives its individual character ('innere Form,' Humboldt, 1903–1936: VII, 86–97) generally display a common unitary principle. However, Humboldt's concept of the 'character of a language' differs substantially from the classificatory typologies put forward by earlier authors, such as J. C. Adelung and the brothers A. W. and F. Schlegel, and should not be mixed up with current linguistic typology, which is very different from Humboldt's in being based on comparative classifications of different languages. Although it has formed the basis for a new focus in (synchronic as well as diachronic) typological linguistic research, linguists have yet to consistently pursue the full implications of Humboldt's typology of language.

Humboldt's approach to the relationship between language, thought, and nationality is intimately linked to his Aristotelian view that language is an intentional creative activity (*enérgeia*) rather than a product fixed once and for all (*érgon*) (Humboldt, 1903–1936: VII, 46). Again, many linguists (see, e.g., **Chomsky, Noam (b. 1928)**) have taken up the important concept of *enérgeia*, yet generally in a fairly loose sense that differs substantially from its original meaning with Humboldt. For Humboldt the notion of *enérgeia* implies that language cannot be studied adequately from a naturalistic point of view (Humboldt, 1903–1936: VI, 151). Language is *enérgeia* because it is a mental process ('geistiger Process,' Humboldt, 1903–1936: VI, 146) that has reality in innumerable acts of speech only, not in a finite set of rules or fixed elements. As a consequence, language use is only partly a realization of an already acquired linguistic knowledge; it is, above all, the free and constant creation of such a knowledge. This also explains why languages unceasingly change (Humboldt, 1903–1936: VI, 243), their history reflecting the history of ideas, more or less corresponding organically to their inner forms, and why for Humboldt language ultimately finds its true realization in the genius of literature.

Humor in Language

N R Norrick, Saarland University, Saarbrücken, Germany

© 2006 Elsevier Ltd. All rights reserved.

There are many spoken and written varieties of humor, from puns to novels, but characteristic techniques recur in all forms of verbal humor, namely production of incongruity based on linguistic constructions or on the events described. Such incongruity can be represented as a clash between opposed semantic scripts. (*see* **Narrative: Linguistic and Structural Theories.**) Thus, in the classic one-liner:

> A panhandler came up to me today and said he hadn't had a bite in weeks, so I bit him.

The phrase "had a bite" belongs structurally to the build-up, while functioning as the script-switch trigger, that is, the unit around which the joke's dual meaning revolves. The script in force in the build-up, namely a panhandler seeking a handout from a passer-by, vanishes in the punchline, where a previously backgrounded script takes hold, in which the victimized passer-by becomes the attacker, while the panhandler becomes the victim. Recognition of the sudden script switch releases psychic energy as laughter, according to Freud (1960), Bateson (1953), and others. (*see* **Freud, Sigmund (1856–1939); Bateson, Gregory (1904–1980).**)

In everyday talk we find both spontaneous conversational joking (puns, banter, wordplay), personal anecdotes, and canned jokes (either narrative or non-narrative, as in riddle jokes). Conversational joking can be spontaneous or formulaic. (*see* **Formulaic Speech.**) Recurrent conversational situations call for formulaic witticisms like "Born in a barn?" to someone who leaves a door open, and typical joking strategies like hyperbole: "I had about a thousand books to return" and irony: "I love it when it sleets." These utterances generate humor through the speaker's pretense in evoking one script while believing another – often modeled theoretically as a violation of some conversational maxim or the principle of relevance. (*see* **Maxims and Flouting; Relevance Theory: Stylistic Applications.**) There are humorous sayings such as, "It's like déjà vu all over again"; allusions like "Though William shake his spear, Anne hath a way"; proverbial similes like "Colder than a well-digger's ass"; leave-taking formulas like "See you in the funny papers"; and so on.

A description of the syntax and semantics of jokes as in Raskin (1985) requires to be extended, in order to include a consideration of their interpersonal and social dimensions in real-life contexts (Attardo, 1994, 1997; Attardo and Raskin, 1991). Discourse analysis has begun to elucidate the performance aspects of joke and anecdote telling (Sacks, 1974; Norrick, 2001), and to explore how conversationalists create and respond to humor in interaction, in casual talk among friends (Norrick, 1993) and family members (Everts, 2003), as well as in institutional settings (Holmes, 2000). (*see* **Critical Discourse Analysis; Institutional Talk.**) We must view joke telling, punning, and teasing in relation to contextualization cues, gender, power, solidarity, and social distance, as well as principles of politeness and cooperation in order to understand how verbal humor can express aggression, yet still build rapport. Joking allows participants to signal their respective affiliations and to align themselves with respect to them. Humor provides a socially acceptable vent for strong emotions toward other people and groups. Some individuals joke with almost everyone; some people kid each other whenever they meet, developing customary joking relationships in which teasing and joking are habitual and competitive. Moreover, conversational humor often revolves around inside jokes – jokes only group members have the shared background knowledge to understand (*see* **Shared Knowledge; Irony; Politeness; Punning**).

Humor: Stylistic Approaches

P Simpson, Queen's University, Belfast, Northern Ireland

© 2006 Elsevier Ltd. All rights reserved.

Much work in stylistics has demonstrated a sustained and thoroughgoing interest in the connections between patterns of style and aspects of verbal humor. This interest stems in part from stylistics' general concern with text analysis and from its preoccupation with developing analytic models to help explain the ways texts function as discourse. Stylisticians are, however, also interested in humorous discourse as it intersects with the wider study of verbal play and creativity in language. This particular approach is embodied in Nash's seminal study (Nash, 1985), which draws upon a large range of texts, penned by the author himself, to illustrate the full spectrum of types of verbal humor. A further dimension of the stylistic analysis of humor, which works in parallel with the focus on the connections between textual patterns and the humor impulse, is its interest in the differences between humorous discourse and so-called 'ordinary' discourse. The concern here is therefore with exploring how the 'nonroutine' communication that is humorous discourse makes for a useful tool for exploring contrastively the more commonplace patterns of everyday social interaction (Simpson, 1998: 35).

An axiom that underpins most stylistic research on humor runs as follows: for a text to be humorous, it must exhibit (at least) some sort of stylistic **incongruity**. Importantly, the incongruity may operate at any level of language or discourse; that is, at any point on a linguistic continuum that extends from lexicogrammar right up to dialogue and discourse. Puns and related forms of verbal play illustrate well the type of incongruity that is situated at the 'grammatical' end of the continuum. The incongruity in puns occurs when some feature of linguistic structure simultaneously combines two unrelated meanings, thereby allowing a 'double meaning' to be located in what is in effect a chance connection between two elements of language. **Lexical** puns, for instance, are activated by a clash between polysemous lexical items such as homophones and homonyms, as in Groucho Marx's quip "We only shot two bucks, but that's all the money we had" (see further Simpson, 2003: 16–29).

Situated toward the opposite end of the continuum, some incongruities may be grounded in mismatches between text and discourse context, and this type of humor-inducing strategy has received fullest explication in stylistic research on drama dialogue. Stylisticians have been especially interested in oppositions between characters' speech strategies and the discourse context (within the play) in which these strategies are framed. Similarly, stylisticians have

Humor: Stylistic Approaches

P Simpson, Queen's University, Belfast, Northern Ireland

© 2006 Elsevier Ltd. All rights reserved.

Much work in stylistics has demonstrated a sustained and thoroughgoing interest in the connections between patterns of style and aspects of verbal humor. This interest stems in part from stylistics' general concern with text analysis and from its preoccupation with developing analytic models to help explain the ways texts function as discourse. Stylisticians are, however, also interested in humorous discourse as it intersects with the wider study of verbal play and creativity in language. This particular approach is embodied in Nash's seminal study (Nash, 1985), which draws upon a large range of texts, penned by the author himself, to illustrate the full spectrum of types of verbal humor. A further dimension of the stylistic analysis of humor, which works in parallel with the focus on the connections between textual patterns and the humor impulse, is its interest in the differences between humorous discourse and so-called 'ordinary' discourse. The concern here is therefore with exploring how the 'nonroutine' communication that is humorous discourse makes for a useful tool for exploring contrastively the more commonplace patterns of everyday social interaction (Simpson, 1998: 35).

An axiom that underpins most stylistic research on humor runs as follows: for a text to be humorous, it must exhibit (at least) some sort of stylistic **incongruity**. Importantly, the incongruity may operate at any level of language or discourse; that is, at any point on a linguistic continuum that extends from lexicogrammar right up to dialogue and discourse. Puns and related forms of verbal play illustrate well the type of incongruity that is situated at the 'grammatical' end of the continuum. The incongruity in puns occurs when some feature of linguistic structure simultaneously combines two unrelated meanings, thereby allowing a 'double meaning' to be located in what is in effect a chance connection between two elements of language. **Lexical** puns, for instance, are activated by a clash between polysemous lexical items such as homophones and homonyms, as in Groucho Marx's quip "We only shot two bucks, but that's all the money we had" (see further Simpson, 2003: 16–29).

Situated toward the opposite end of the continuum, some incongruities may be grounded in mismatches between text and discourse context, and this type of humor-inducing strategy has received fullest explication in stylistic research on drama dialogue. Stylisticians have been especially interested in oppositions between characters' speech strategies and the discourse context (within the play) in which these strategies are framed. Similarly, stylisticians have

reached interesting conclusions about the humor mechanism by crossreferencing the way fictional characters interact on the stage with the way they might be expected to interact should they inhabit the 'real' interactive world of playwright and audience/reader. Indeed, this tradition of research has yielded many insightful studies of the Theatre of the Absurd, where rich comparisons can be drawn between the discourse world **inside** the play and the discourse world **outside** the play (see Burton, 1980; Short, 1989; Simpson, 2000; Herman, 1996). By way of illustration, consider the following short scene from N. F. Simpson's absurdist play *One Way Pendulum*, where a courtroom has been hastily assembled inside a domestic living room to facilitate Mr. Groomkirby's 'swearing in' ceremony:

> The Usher enters followed by Mr. Groomkirby, whom he directs into the witness box. Mr. Groomkirby takes the oath.
> Mr. Groomkirby: (*holding up a copy of* Uncle Tom's Cabin).
> I swear, by Harriet Beecher Stowe, that the evidence I shall give shall be the truth, the whole truth, and nothing but the truth.
> Judge: You understand, do you, that you are now on oath?
> Mr. Groomkirby: I do, m'lord (Simpson, 1960: 60).

Whereas a courtroom is an institutionally designated location that deals exclusively with legal proceedings, it manifestly cannot be set up *ad hoc* in a domestic living room. Moreover, there are established procedures for ritualized activities such as the swearing-in of witnesses, and shared assumptions between participants about the way these routines are conducted form part of the communicative context of a 'real' courtroom. Clearly, the 'swearing in' ceremony here violates the pragmatic preconditions that govern the ritual, and so the communicative competence that organizes everyday interaction for the reader/viewer of the play acts as a frame for interpreting the incongruity of the displayed interaction at the character level on stage.

The principle of incongruity as a humor-inducing technique can be extended, beyond its core sense as a stylistic twist in a pattern of language, to cover situations where there is a mismatch between what someone says and what they mean. This extended pragmatic sense equates roughly with the concept of **irony**. Many forms of irony are situated in a discursive opposition between what is asserted and what is meant, as embodied in an utterance such as 'You're a fine friend!' when said to someone who has just let you down. The irony here is located in a departure from Grice's maxim of 'truth' (which dictates that your interactive contribution must be true), although not all irony is explicable within the Gricean model. For example, another conceptual framework, arising from work in Relevance Theory, sees irony as 'echoic mention'; that is, as a type of usage where the utterance echoes other utterances and forms of discourse. This is apparent in an exchange such as the following

> A: I'm really fed up with this washing up.
> B: *You're fed up!* Who do you think's been doing it all week?

where the proposition about being fed up is used in a 'straight' way by the first speaker, but in an ironic, echoic way by the second (see Sperber and Wilson, 1981).

Irony, in both of the senses identified above, features especially prominently in stylistic research on parody and satire – two forms of verbal humor whose central stylistic incongruities are arguably built upon different kinds irony. The principle of echoic mention is absolutely central to parody's capacity to function as what Nash terms 'a discourse of allusion' (Nash, 1985: 100). Parody can take any particular anterior text as its model, although more general characteristics of other genres of discourse can also be brought into play. Once echoed, the stimulus text becomes part of a new discourse context so it no longer has the illocutionary force it once had in its original context, and that is what often engenders parody's ironic humor.

Satire has an aggressive element which is not necessarily present in parody. How this translates into stylistic terms is that satirical discourse, as well as having an echoic element, requires a further kind of ironic twist or distortion, of the more 'Gricean kind,' in its textual design. This additional distortion means that while parodies can remain affectionate to their source, satire can never be so. To illustrate, consider this famous passage from Jonathan Swift's satirical pamphlet *A Modest Proposal*:

> I shall now therefore humbly propose my own thoughts, which I hope will not be liable to the least objection. I have been assured by a very knowing American of my acquaintance in London, that a young healthy child well nursed is at a year old a most delicious, nourishing, and wholesome food, whether stewed, roasted, baked, or boiled; and I make no doubt that it will equally serve in a fricassee or a ragout (Swift, 1986 [1729]: 2175–2176).

The 'echoic irony' in Swift's text derives from its mimicking of the genre of the early eighteenth century pamphlet, and more narrowly the proliferation of pamphlets offering economic solutions to what was then perceived as the 'Irish problem.' However, the passage also contains an ironic distortion that marks it out as satire. This distortion comes through the

startling sequence where the persona proposes to alleviate the burden of overpopulation and starvation in Ireland by eating that country's children. This twist marks an abrupt shift from a framework embodying what is morally acceptable to a framework of abnormality and obscenity.

An important rider needs to be attached to the 'incongruity-based' stylistic work on humor sketched thus far, which is, to put it bluntly, that not all incongruities are funny. Indeed, the type of humor response that a single textual stimulus attracts can vary enormously from recipient to recipient and from context to context. The variability of the humor response has not escaped the attention of stylisticians, and more recent work in stylistic humorology has sought to address both sides, the stimulus and the response side, of the humor event. One model that has come to prominence in this respect is the *General Theory of Verbal Humor* (GTVH) (see Attardo 1997, 2001 for useful compact expositions of the model). A key postulate of the GTVH is that the incongruity element in a humorous text is bounded by a preceding 'setup phase,' which establishes a neutral context for the incongruity, and a 'resolution phase,' which describes the knowledge resources employed by the humor processor to resolve the incongruity. The GTVH thus marks a shift away from an entirely text-centered description of humor toward one that accords equal weight to both textual and cognitive mechanisms of humor processing.

A useful literary-stylistic application of the GTVH is Attardo (2002), which is an exploration of the techniques of verbal humor used in Oscar Wilde's *Lord Arthur Savile's Crime*. Of a number of extensions to the theoretical model, Attardo develops a mechanism for exploring the humor of longer texts– the GTVH traditionally concerns itself with short jokes and quips – part of which involves differentiating between 'punch lines' and 'jab lines.' In multiple joke-bearing texts, the punch line is a humorous instance at the end of a text, while the jab line is a humor instance anywhere else in a text (Attardo, 2002: 235).

Another area where stylistic investigation has sought to move beyond textual description to consider the sociopragmatic features of humor is Simpson's study of satirical discourse (Simpson, 2003). Simpson seeks to isolate the inferencing mechanisms that text processors need to use in order for a text to become satire. Especially important is the mechanism that allows a text's claim to 'sincerity' to be rescinded – a mechanism that is normally pressed into service on encountering ironic distortions like those sketched earlier. Translated to Swift's satirical text quoted above, the distortion at the textual level results, probably for most readers, in the sincerity condition being rescinded at the pragmatic level, the perlocutionary consequence of which is that the text is read as satire and not as a 'straight' or serious proposal.

Contemporary stylistic approaches to verbal humor will continue to develop models of analysis where descriptions of text are paralleled with descriptions of the text's impact, both social and cognitive, on its readers. One area that is yet to receive adequate scholarly scrutiny is to do with the intersection between humor and other stylistic devices. For instance, while a technique such as literary **foregrounding** relies on an incongruity in its textual design, there remains no adequate account of why some, but not all, foregrounded patterns in a text are funny. The same principal applies to figurative language, where the question again arises as to why, for example, some novel metaphors and metonymies are humorous and some are not. These questions will no doubt be addressed by stylisticians as ever more sophisticated methods of dealing with humorous language present themselves.

History

Hungarian is a member of the Finno-Ugric branch of the Uralic language family. The Finno-Ugric peoples represented a kind of linguistic and areal unity, populating the southwestern slopes of the Ural Mountains, until 2000 B.C. Hungarian emerged from among the Ugric dialects around 1000 B.C. The Hungarian tribes left the Finno-Ugric homeland in 500 A.D. and occupied the territory surrounded by the Carpathian Mountains in 895, where they established a Hungarian Kingdom in 1000.

The first written records are Hungarian fragments in a Greek and a Latin text, dating from 950 and 1055, respectively. The first surviving coherent written Hungarian text originated in 1192–1195.

Hungarian has about 13.5 million native speakers, the largest number of speakers in the Uralic language family, 10 million of which live in Hungary. The Versailles Treaties in 1920 annexed one-third of Hungarian native speakers – together with two-thirds of the territory of Hungary – to neighboring countries. As a consequence, Romania now has 1.6 million indigenous Hungarian speakers; Slovakia has 520 000; Serbia-Montenegro, 290 000; Ukraine, 156 000; Croatia, 16 000; Slovenia, 7000; and Austria, 4000. The number of Hungarian speakers in the United States, Australia, and Western Europe is around one million.

Hungarian is fairly homogeneous areally; the only dialect displaying substantial lexical, phonological, and syntactic differences from standard Hungarian is the easternmost, archaic Csángó dialect in Romania.

Names for the Language

Hungarians call themselves and their language *magyar*. Others refer to them by variants of the ancient tribal name *Onogur* (e.g., *Hungarian, ungarisch, vengerski*).

Language Description

Phonology

Hungarian has the following 14 vowels: a[ɔ], á[a:], e[ɛ], é[e:], i[i], í[i:], u[u], ú[u:], ü[y], ű[y:], o[o], ó[o:], ö[ø], ő[ø:]. (In each pair of symbols, the first one is

History

Hungarian is a member of the Finno-Ugric branch of the Uralic language family. The Finno-Ugric peoples represented a kind of linguistic and areal unity, populating the southwestern slopes of the Ural Mountains, until 2000 B.C. Hungarian emerged from among the Ugric dialects around 1000 B.C. The Hungarian tribes left the Finno-Ugric homeland in 500 A.D. and occupied the territory surrounded by the Carpathian Mountains in 895, where they established a Hungarian Kingdom in 1000.

The first written records are Hungarian fragments in a Greek and a Latin text, dating from 950 and 1055, respectively. The first surviving coherent written Hungarian text originated in 1192–1195.

Hungarian has about 13.5 million native speakers, the largest number of speakers in the Uralic language family, 10 million of which live in Hungary. The Versailles Treaties in 1920 annexed one-third of Hungarian native speakers – together with two-thirds of the territory of Hungary – to neighboring countries. As a consequence, Romania now has 1.6 million indigenous Hungarian speakers; Slovakia has 520 000; Serbia-Montenegro, 290 000; Ukraine, 156 000; Croatia, 16 000; Slovenia, 7000; and Austria, 4000. The number of Hungarian speakers in the United States, Australia, and Western Europe is around one million.

Hungarian is fairly homogeneous areally; the only dialect displaying substantial lexical, phonological, and syntactic differences from standard Hungarian is the easternmost, archaic Csángó dialect in Romania.

Names for the Language

Hungarians call themselves and their language *magyar*. Others refer to them by variants of the ancient tribal name *Onogur* (e.g., *Hungarian, ungarisch, vengerski*).

Language Description

Phonology

Hungarian has the following 14 vowels: a[ɔ], á[a:], e[ɛ], é[e:], i[i], í[i:], u[u], ú[u:], ü[y], ű[y:], o[o], ó[o:], ö[ø], ő[ø:]. (In each pair of symbols, the first one is

the letter denoting the phoneme; the second is its phonetic transcription.) The vowels form pairs differing in length; single or double accents mark long vowels. Hungarian displays vowel harmony; stems (except some recent borrowings) contain either only front vowels (ö, ő, ü, ű) and neutral vowels (e, é, i, í), or back vowels (a, á, o, ó, u, ú) and neutral vowels. Suffixes having both front-vowel and back-vowel allomorphs also participate in vowel harmony – (e.g., *kert-ész-ünk-kel* garden-er-our-with/*fodr-ász-unk-kal* style-ist-our-with).

The number of consonant phonemes is 24: p, b, t, d, ty[t^y], gy[d^y], k, g, f, v, sz[s], z, s[š], zs[ž], h, c[t^s], cs[č], dzs[j], m, n, ny[n^y], l, r, j. The letter combination *ly*, occurring in a small set of words, has the same phonetic value as *j*. Consonants also have long versions, indicated by doubling. Adjacent consonants at morpheme boundaries are subject to assimilation processes, among them voicing assimilation:

dob-t-am [do**pt**am]
throw-PAST-1SG
tép-d [té**bd**]
tear-IMP.2SG

Word stress falls on the first syllable of words, and phrasal stress falls on the first major category of phrases.

Morphology

Hungarian is an agglutinating language. Nouns are inflected for number and case. There are 18 cases, among them a rich system of adverbial cases denoting various location, goal, and source relations:

ház-ban
house-INESS
'in house'
ház-ba
house-ILLAT
'into house'
ház-ból
house-ELAT
'from house'

Possessed nominals bear a possessedness marker and a morpheme agreeing in person and number with the possessor:

lány-a-i-m-at
daughter-POSS-PL-1SG-ACC
'my daughters'

Verbs are marked for tense (present or past), marked for mood (indicative, imperative/subjunctive, or conditional), and bear an agreement suffix indicating the person and number of the subject.

vár-ok
wait-(PRES)-1SG
vár-t-ál
wait-PAST-2SG
vár-j-on
wait-IMP-3SG
vár-ná-nk
wait-COND-1PL
vár-t-ak vol-na
wait-PAST-3PL AUX-COND
'they would have waited'

Definite objects elicit the object-agreement suffix-*ja/e/i* (*lát-**já**-tok őt* see-OBJ-2PL him 'you see him'), which in many cases fuses with the subject agreement morpheme, yielding an objective conjugation. Verb stems usually denote processes or states; telic accomplishments and achievements are mostly derived by means of verbal particles prefixed to the verb: *eszik* 'eats' – *meg-eszik* up eats; *megy* 'goes' – *be-megy* in goes. Hungarian lacks passive voice. Infinitives selected by an impersonal matrix predicate have their own dative-marked subject, with which they agree in person and number.

Postpositions also agree in number and person with their pronominal complement:

mi mellett-ünk
we near-1PL
'near us'

ti után-atok
you-after-2PL
'after you'

Syntax

The Hungarian sentence displays a 'Topic Focus V XP' order. The topic, or topics, names the referent(s) that the sentence is about. Any argument can serve as topic:

***Jánosnak** oda-adta Péter a könyvet*
John-DAT PRT gave Peter the book

***Péter** oda-adta Jánosnak a könyvet*
Peter PRT gave John-DAT the book

***A könyvet** oda-adta Péter Jánosnak*
the book-ACC PRT gave Peter John-DAT

The immediately preverbal focus is the prosodically and pragmatically most emphatic constituent. If represented by a definite or a specific indefinite noun phrase, it expresses exhaustive identification. Thus *Péter JÁNOSNAK adta oda a könyvet* means 'It was to John that Peter gave the book'; *A könyvet PÉTER adta oda Jánosnak* means 'It was Peter who gave the book to John'. The postverbal order of

arguments is free. Universally quantified phrases such as *mindenki* 'everybody', *minden fiúnak* all boy-DAT 'to all the boys' stand between the topic and the focus. The verb, the focus, or both can be preceded by a negative particle: ***Nem** JÁNOS **nem** vett autót* not John not bought car 'It wasn't John who did not buy a car'. The negative particle triggers negative concord: *Senki nem vett semmit* nobody not bought nothing 'Nobody bought anything'. Interrogative phrases appear in the preverbal focus position (e.g., *János kit szeret?* John whom loves 'Who does John love?').

The noun phrase is head-final. Articles and attributive adjectives do not agree with the head noun. Numerals block the plural marking of the noun: *két piros alma* two read apple.

Hungarian is a pro-drop language. When combined with phonetically null morphemes, the copula is also dropped, cf.: *Éva beteg* Eve sick 'Eve is sick' – *Éva beteg vol-t* Eve sick be-PAST 'Eve was sick', *Beteg vagy-ok* sick be-1SG 'I am sick').

Explanatory Dictionaries

The seven-volume monolingual dictionary of Hungarian, *A magyar nyelv értelmező szótára I–VII*, created during the 1950s by Bárczi and Országh (1959–1962), is the largest Hungarian dictionary of its type. Although today considered outdated from several viewpoints (entry selection, usage labels, grammar, etc.), it was recently published in electronic format, giving a new life to this old work. It contains some authentic quotations from Hungarian fiction, although not necessarily pertaining to each sense.

Based on the Bárczi and Országh seven-volume dictionary, a slightly modernized and considerably abridged one-volume version was compiled in the 1960s by Juhász *et al*. (1972). This work, *Magyar értelmező kéziszótár*, is still the most commonly used Hungarian monolingual dictionary. In the updated and corrected version by Pusztai (2003), a considerable effort was made to refresh the vocabulary of the dictionary, not only with neologisms, but also with several words from the vocabulary of Hungarians living outside present-day Hungary. Although a new, corpus-based monolingual dictionary of Hungarian has been impossible to produce due to the lack of financial and human resources, a 150-million-word synchronic electronic corpus of Hungarian was used at the final stage of Pusztai's 2003 edition to create a frequency index. The CD version of the dictionary has been published as well.

Historical Dictionaries

Some small historical dictionaries were compiled during the 19th century (see Budenz, 1873–1881; Szarvas and Simonyi, 1890–1893; Szily, 1902–1908). A new project for creating the *Historical dictionary of Hungarian,* underway for some years, currently aims to produce an eight-volume dictionary with some 100 000 entries, covering the period between 1772 and 2000. The entries are based on a 25-million-word electronic historical corpus, but also include the old-fashioned, hand-written dictionary slips. Each sense of each headword will be illustrated by corpus examples, including bibliographic reference to the sources. The first volume will contain letters A and B.

Another project (Szabó, 1975–2002) has been in progress for several decades; the goal is to collect and explain the words occurring in old documents

arguments is free. Universally quantified phrases such as *mindenki* 'everybody', *minden fiúnak* all boy-DAT 'to all the boys' stand between the topic and the focus. The verb, the focus, or both can be preceded by a negative particle: ***Nem** JÁNOS **nem** vett autót* not John not bought car 'It wasn't John who did not buy a car'. The negative particle triggers negative concord: *Senki nem vett semmit* nobody not bought nothing 'Nobody bought anything'. The CD version of the dictionary has been published as well.

Historical Dictionaries

Some small historical dictionaries were compiled during the 19th century (see Budenz, 1873–1881; Szarvas and Simonyi, 1890–1893; Szily, 1902–1908). A new project for creating the *Historical dictionary of Hungarian,* underway for some years, currently aims to produce an eight-volume dictionary with some 100 000 entries, covering the period between 1772 and 2000. The entries are based on a 25-million-word electronic historical corpus, but also include the old-fashioned, hand-written dictionary slips. Each sense of each headword will be illustrated by corpus examples, including bibliographic reference to the sources. The first volume will contain letters A and B.

Another project (Szabó, 1975–2002) has been in progress for several decades; the goal is to collect and explain the words occurring in old documents

and archives in Transylvania, a region of historical Hungary. Old manuscripts serve as resources, and each sense of each word is illustrated with authentic quotations with exact bibliographic reference.

Etymological Dictionaries

The most reliable etymological dictionary of Hungarian (see Benkő, 1967–1976) contains the etymology of the 10 000 most basic Hungarian words, based on and citing the earliest quotations found in archives or in printed sources. The updated German version (Benkő, 1993–1997) has made the Hungarian scholarly lexicography available to international expert users.

A specialized etymological dictionary of geographical names (see Kiss, 1988) mainly concentrates on place-names and features of the Carpathian basin, but it also includes well-known international names.

Other Monolingual Dictionaries

The first scholarly synonymic dictionary of Hungarian (see O. Nagy and Ruzsiczky, 1978) was followed by a new popular edition by Kiss (1998). Two brand-new phrasal dictionaries were published in 2003 (Bárdosi, 2003; Forgács, 2003); the Forgács volume was based on an electronic corpus of Hungarian newspapers.

Bilingual Dictionaries

After a centuries-long tradition of bilingual dictionary publishing, most of the earlier compiled dictionaries have now been thoroughly updated and republished (see Eckhardt and Konrád, 1999; Eckhardt and Oláh, 1999; Országh *et al.*, 1999; Országh and Magay, 2000; Halász *et al.*, 2002a,b). Several brand-new dictionaries have also been produced (e.g., Pálfy, 1999; Hessky, 2000, 2002; Perrot, 2000; Mollay, 2002). These user-friendly dictionaries employ up-to-date resources of international lexicography, including several example sentences, collocations and idioms, and systematic information on valencies. All of the most recently published dictionaries are computer-based and were either directly entered in extensible markup language (XML) format or were converted to this format at the end of the edition. They have all been published in compact disc (CD) format as well.

The Lexicographic Committee of the Hungarian Academy of Sciences

The Lexicographic Committee of the Hungarian Academy of Sciences was reestablished in 2000. Its main aim is to support scholarly lexicography, to coordinate the work of independent dictionary makers, and to help organize different levels of lexicography teaching at universities. One of the first and most important efforts of the committee was to compile a full bibliography of existing Hungarian dictionaries (Magay, 2004).

Hungarian: Phonology

R M Vago, City University of New York, New York, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

The phonology of Standard Hungarian has proved to be challenging from both the descriptive and theoretical points of view. Notable analytical treatises of the major patterns of the Hungarian sound system, with discussion of their impact on various theoretical models, include (among others) those of Hetzron (1972), Vago (1980), Abondolo (1988), Olsson (1992), Szende (1992), Kiefer (1994), Kornai (1994), Ritter (1995), Szigetvári (1999), Siptár and Törkenczy (2000), Hunyadi (2002), and Varga (2002). For detailed descriptions of the Hunagarian phonology, including elaborate citation of examples, exceptions, and vacillations, as well as variations in dialect, register, style, and speech tempo, see especially Vago (1980), Kenesei *et al*. (1998), Kiefer (1994) – notably the contributions of Siptár, Törkenczy, Nádasdy, and Varga – and Siptár and Törkenczy (2000), and references cited therein.

Phonemics

In the following descriptions of the Hungarian consonant and vowel phonemes, the orthographic representations are in italics and the phonemic representations (in terms of International Phonetic Alphabet symbols) are within slashes; this is followed by a description of the articulation; the significant allophones, if any, are within brackets.

Consonants

Hungarian consonants that are intervocalic or syllable final before pause (except for [h]) may be geminate (long). Geminates occur both underlyingly and in derived contexts as a result of morpheme concatenation ('fake' geminates) or assimilation; [vv] and [ʒʒ] are found only in derived environments. Orthographically, gemination is indicated with double letters; in the case of digraphs, only the first letter is doubled (e.g., short *sz* [s] vs. long *ssz* [ss]). Hungarian consonants are defined as follows:

p /p/: Voiceless unaspirated bilabial stop.
t /t/: Voiceless unaspirated dental stop.
ty /c/: Voiceless unaspirated palatal stop.
k /k/: Voiceless unaspirated velar stop.
c /ts/: Voiceless unaspirated dental affricate. This phoneme is voiced to [dz] before voiced obstruents by a general voicing assimilation process (see later, Obstruent Voicing Assimilation). For arguments that [dz] is not phonemic, see Kiefer (1994), Kenesei *et al*. (1998), and Siptár and Törkenczy (2000).
cs /tʃ/: Voiceless unaspirated alveopalatal affricate.
b /b/: Voiced bilabial stop.
d /d/: Voiced dental stop.
gy /ɟ/: Voiced palatal stop.
g /g/: Voiced velar stop.
dzs /dʒ/: Voiced alveopalatal affricate (rare).

Hungarian: Phonology

R M Vago, City University of New York, New York, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

The phonology of Standard Hungarian has proved to be challenging from both the descriptive and theoretical points of view. Notable analytical treatises of the major patterns of the Hungarian sound system, with discussion of their impact on various theoretical models, include (among others) those of Hetzron (1972), Vago (1980), Abondolo (1988), Olsson (1992), Szende (1992), Kiefer (1994), Kornai (1994), Ritter (1995), Szigetvári (1999), Siptár and Törkenczy (2000), Hunyadi (2002), and Varga (2002). For detailed descriptions of the Hunagarian phonology, including elaborate citation of examples, exceptions, and vacillations, as well as variations in dialect, register, style, and speech tempo, see especially Vago (1980), Kenesei *et al*. (1998), Kiefer (1994) – notably the contributions of Siptár, Törkenczy, Nádasdy, and Varga – and Siptár and Törkenczy (2000), and references cited therein.

Phonemics

In the following descriptions of the Hungarian consonant and vowel phonemes, the orthographic representations are in italics and the phonemic representations (in terms of International Phonetic Alphabet symbols) are within slashes; this is followed by a description of the articulation; the significant allophones, if any, are within brackets.

Consonants

Hungarian consonants that are intervocalic or syllable final before pause (except for [h]) may be geminate (long). Geminates occur both underlyingly and in derived contexts as a result of morpheme concatenation ('fake' geminates) or assimilation; [vv] and [ʒʒ] are found only in derived environments. Orthographically, gemination is indicated with double letters; in the case of digraphs, only the first letter is doubled (e.g., short *sz* [s] vs. long *ssz* [ss]). Hungarian consonants are defined as follows:

p /p/: Voiceless unaspirated bilabial stop.
t /t/: Voiceless unaspirated dental stop.
ty /c/: Voiceless unaspirated palatal stop.
k /k/: Voiceless unaspirated velar stop.
c /ts/: Voiceless unaspirated dental affricate. This phoneme is voiced to [dz] before voiced obstruents by a general voicing assimilation process (see later, Obstruent Voicing Assimilation). For arguments that [dz] is not phonemic, see Kiefer (1994), Kenesei *et al*. (1998), and Siptár and Törkenczy (2000).
cs /tʃ/: Voiceless unaspirated alveopalatal affricate.
b /b/: Voiced bilabial stop.
d /d/: Voiced dental stop.
gy /ɟ/: Voiced palatal stop.
g /g/: Voiced velar stop.
dzs /dʒ/: Voiced alveopalatal affricate (rare).

f /f/: Voiceless labiodental fricative.

sz /s/: Voiceless dental fricative.

s /ʃ/: Voiceless alveopalatal fricative.

h /h/: Voiceless glottal fricative, exhibiting the following allophonic distribution: [h] prevocalically, voiced glottal fricative [ɦ] between sonorant segments and vowels, voiceless velar fricative [x] after back vowels in the coda of a syllable (that is, either word finally or before consonants), and voiceless palatal fricative [ç] (or a fronted version of [x]) after front vowels in coda positions (see later, /h/-Deletion, for further discussion).

v /v/: Voiced labiodental fricative.

z /z/: Voiced dental fricative.

zs /ʒ/: Voiced alveopalatal fricative.

m /m/: Voiced bilabial nasal, becoming labiodental [ɱ] before the labiodentals /f/ and /v/.

n /n/: Voiced dental nasal, having allophonic variants that reflect the place of articulation of a following labiodental, alveopalatal, or velar consonant (as part of a general assimilation process; see later, Nasal Assimilation).

ny /ɲ/: Voiced palatal nasal.

l /l/: Voiced dental lateral.

r /r/: Voiced dental trill.

j, ly /j/: Voiced palatal glide, having the following two allophones: voiceless palatal fricative [ç] in word-final position following a voiceless consonant, and voiced palatal fricative [j̊] in word-final position following a voiced consonant (in both cases, word-final position means either before pause or before a consonant-initial word, i.e., when /j/ can not be resyllabified into the onset position of a following syllable) But see Siptár and Törkenczy (2000) for arguments that /j/ should be classified as a liquid.

Vowels

Hungarian has 14 contrastive vowels; their phonological classifications vary across theories and analyses. The phonemic vowel inventory divides into seven short and seven long vowels. The quantitative difference is accompanied by qualitative differences in the case of nonhigh vowels.

i /i/: Short high front unrounded.

í /iː/: Long high front unrounded.

ü /y/: Short high front rounded (alternatively identified as /ü/).

ű /yː/: Long high front rounded (alternatively identified as /üː/).

u /u/: Short high back rounded.

ú /uː/: Long high back rounded.

e /ɛ/: Short upper low front unrounded.

é /eː/: Long upper mid front unrounded.

ö /œ/: Short lower mid front rounded (alternatively identified as /ö/or/ø/).

ő /øː/ Long upper mid front rounded (commonly identified as /öː/).

o /ɔ/: Short lower mid back rounded (commonly identified as /o/).

ó /oː/: Long upper mid back rounded.

a /ɒ/: Short upper low back rounded (commonly identified as /ɔ/). This vowel is assumed to be unrounded underlyingly, due to its morphophonemic patterning (see, for example, Vago (1980) and Siptár and Törkenczy (2000)). With this caveat, the phonemic symbol used here will reflect the phonetics.

á /ɑː/: Long lower low back unrounded (alternatively identified as central /aː/).

As expected, vowels become (slightly) nasalized before nasal consonants. The only other allophonic variation of note is the fact that under certain conditions of length variation, the nonhigh short vowels, which differ qualitatively from their long counterparts (cf. *e* /ɛ/ vs. *é* /eː/, ö /œ/ vs. *ő* /øː/, *o* /ɔ/ vs. *ó* /oː/, and *a* /ɒ/ vs. *á* /ɑː/), retain their quality distinctions. Thus, with respect to the process of compensatory lengthening (q.v.), *e* /ɛ/ lengthens to [ɛː], ö /œ/ lengthens to [œː], *o* /ɔ/ lengthens to [ɔː], and *a* /ɒ/ lengthens to [ɒː], and conversely, under surface vacillation of vowel duration, *é* /eː/, *ő* /øː/, *ó* /oː/, and *á* /ɑː/ shorten to [e], [ø], [o], and [ɑ], respectively.

Hungarian lacks underlying diphthongs. Nonsyllabic [u] ([w]) may form diphthongs with preceding low vowels, but only in a restricted set of loanwords, and in predictable phonological contexts.

Phonotactics

This discussion of phontactics is concerned with the most significant statements and generalizations regarding the permissible and impermissible segments and clusters of segments within words and syllables.

Syllables

The following template characterizes the segmental constitution of Hungarian syllables on the surface: (C) (C) (C)V(V) (C) (C) (C). With this template, syllables can contain a short vowel (V), a long vowel (VV), and up to three consonants (C) syllable initially and/or syllable finally. Any vowel can be the nucleus, whether followed by a coda or not, although some syllable types are subject to word-level restrictions (see the following subsections). Some of the syllable shapes have limited distribution or have segmental constraints; these are developed in the subsequent subsections.

Following generally accepted nomenclature, V is the nucleus of the syllable, prevocalic C is the onset, and postvocalic C is the coda; the nucleus and the coda together form the rhyme of the syllable. (An alternative syllabic organization gathers some or all of the segments of a syllable into morae, or weight units, rather than into onset/nucleus/coda constituents.) Based in part on phonotactic considerations, some peripheral consonants of a syllable may be best viewed in terms of an appendix constituent, rather than an onset or coda. On this view, Kiefer (1994) and Siptár and Törkenczy (2000) analyzed the basic Hungarian syllable as containing at most one consonant in the onset and at most two consonants in the coda. Nevertheless, for the sake of maximal clarity and utility of the facts, the ensuing generalizations are based on surface representations and are therefore independent of theory-specific analyses.

Intrasyllabic Restrictions There are no ostensible restrictions between the onset and the nucleus on the one hand, and between the onset and the coda on the other. Within the rhyme, two restrictions hold between the nucleus and the coda: (1) if the coda contains a bilabial consonant cluster (/mp/ or /mb/), then the nucleus must have a rounded vowel (phonetically – since /ɒ/, for which, it will be recalled, is rounded only on the surface, is included); (2) in monosyllabic root morphemes ending in a long vowel and a consonant cluster, the nucleus is either /e:/ or /ɑ:/, and the coda can not be a geminate (with few exceptions).

Syllabification As in just about all languages, an intervocalic single consonant must be syllabified as an onset: V.CV (the period indicates a syllable boundary). This generalization holds true within the phonological word: onset syllabification takes place within a morpheme as well as across suffixes, but is blocked between independent words, across a compound boundary, and between a preverb and a verb.

In the case of intervocalic CC sequences, the first C is syllabified into coda position, the second into onset position, i.e., VC.CV (intervocalic geminates are ambisyllabic). Again, the domain is the phonological word. If the intervocalic CC cluster is a possible word-initial cluster, then V.CCV syllabification is also possible, but only tautomorphemically. Thus, *ablak* 'window' may be syllabified either as *ab.lak* or *a.blak* (cf. *blúz* 'blouse'), but *láb-ra* 'onto (the) leg' may be syllabified only as *láb.ra*, even though *br* is a possible word-initial cluster (cf. *brácsa* 'viola').

Intervocalic CCC (and longer) consonant clusters follow the syllabification pattern of intervocalic CC clusters, but with two extra twists. First, if CCC is a permissible word-initial cluster, then three syllabifications are possible: e.g., *ost.rom*/*os.trom*/*o.strom* 'siege' (cf. *strand* 'beach'). Second, if the first two consonants are not permitted in coda position, then VCC.CV syllabification is disallowed: e.g., in *konflis kocsi* 'hansom-cab', the syllabification *konf.lis* is illicit since *nf* is not a possible coda.

Words: Consonant Positions

Word-Initial Consonants All consonants may occur at the beginning of a word, though /c/ is found only in one nominal root and in one interjection, and /ʤ/ is found only in some 20 words, all loans originally.

Word-Final Consonants All consonants may occur at the end of a word, with the exception of [h] (see later). In monosyllabic roots consisting of an initial consonant cluster, a short vowel, and a final single consonant, the latter must be a voiced obstruent.

Word-Initial Consonant Clusters Geminates are precluded in word-initial position. In initial CC clusters, the first C is an obstruent; the second C is almost exclusively a liquid (/l r/), or if the first C is /s/ or /ʃ/, nasal (/m n ɲ/), voiceless stop (/p t c k/), or labiodental (/f v/). In initial CCC clusters, the first C is /s/ or /ʃ/, the second C is a voiceless stop (/p t k/), and the third C is a liquid (/l r/).

Word-Final Consonant Clusters Geminates, save for /ʒʒ/ and /vv/, may occur word finally. Some are underlying only (tautomorphemic), but others can be either underlying or derived (through morphophonemic processes); /zz/ occurs only in derived contexts. Monosyllabic roots containing an initial consonant cluster followed by a short vowel cannot end in a voiced geminate.

Other final CC clusters (basic and derived) are mostly obstruent + obstruent, nasal + obstruent, liquid + obstruent, liquid + nasal, glide + obstruent, and glide + nasal. Final CCC clusters arise mainly through affixation; in roots they occur in a very limited number of loanwords (less than a dozen).

Word-Medial Consonant Clusters Heteromorphemic consonant clusters in word-medial position are subject to various morphophonemic processes (see later, Morphophonemics). In general, the prohibited heteromorphemic consonant cluster sequences are banned tautomorphemically as well. This is seen very clearly in the case of obstruent clusters. Derived obstruent clusters undergo voicing assimilation; in the same vein, underlying obstruent clusters must agree in voicing.

All consonants may occur as geminates in word-medial position, most of them in both underlying and derived contexts (word-medial /vv/ and /ʒʒ/ are always derived). Medial CCC clusters are almost exclusively derived through affixation. About 100 root morphemes (loans in origin) contain less than 10 medial CCC combinations. Medial CCC clusters are even rarer; a medial CCCCC cluster is found only in one word (*angström* [ɒŋkʃtrœm] 'angstrom').

Words: Vowel Positions

Word-Initial Vowels All vowels, short and long, may occur in word-initial position.

Word-Final Vowels All vowels (short and long), except /ɔ/ and /œ/ (more generally, these vowels may not occur morpheme finally), can occur in word-final position, with the following provisos: (1) In monosyllabic content words, final short vowels (light syllables) are disallowed (except in two cases). This prohibition fixes the length of Hungarian content words as minimally bimoraic (or its equivalent): words must either be monosyllabic, ending in a long vowel or closed by a consonant, or else polysyllabic. (2) Also prohibited is word-final /ɑː/ in underived roots (with few exceptions). (3) Word-final /iː/ occurs in less than five content words.

Vowel Sequences Some sequences of vowels derived by suffixation are eliminated by morphophonemic processes (see later). Otherwise, both underlying and derived vowel sequences are realized phonetically as follows: they either are broken up by an intrusive [j], or surface with hiatus. In general, intrusive [j] shows up between /eː/ sequences or if one of the adjacent vowels is /i/ or /iː/; hiatus obtains between any combination of low vowels and rounded vowels, and between identical vowels (except for /i/, /iː/, or /eː/, as per the preceding clause).

Morphophonemics

The following discussions of morphophonemics address the most salient segmental alternations of the language. General, across-the-board processes are described first. Nongeneral processes, i.e., unproductive, morpheme-specific, and lexically conditioned processes (though some may be predictable phonologically), are then addressed. Throughout, the following word constitution is assumed: underived roots or roots plus derivational suffixes make up the stem, followed by inflectional suffixes. The appearance and quality of linking vowels and apparent exceptions in the suffix system are not discussed here.

Assimilation

Vowel Harmony No other aspect of the phonology of Hungarian has attracted the interest of phonologists more than the phenomenon commonly referred to as vowel harmony. This process has been well described and analyzed and has made significant contributions to issues in a wide array of theoretical frameworks, including generative/rule based (Vago, 1976, 1980; Reiss, 2003), autosegmental (van der Hulst, 1985; Kornai, 1990; Kiefer, 1994; Siptár and Törkenczy, 2000), government (Ritter, 1995; Polgárdi, 1998), and optimality (Ringen and Vago, 1998), just to mention some, with highly selective references.

As a general rule, back vowels and front rounded vowels do not co-occur within the domain of the phonological word. This regularity is enforced both within roots as well as for suffixes. The system is root controlled in that the harmonic category of roots determines the harmonic shapes of suffixes, which have front and back alternants: *u/ü*, *ú/ű*, *ó/ő*, *a/e*, *á/é*, and *o/ö*. The last pair has a third alternant: *o* occurs after roots that govern back harmony in suffixes, and *ö* or *e* occurs after roots that govern front harmony in suffixes. The choice between *ö* and *e* is determined by the immediately preceding vowel (generally referred to as rounding harmony): *ö* occurs after rounded (front) vowels and *e* occurs after unrounded (front) vowels (one suffix is exceptional: it lacks the *e* variant). In particular, roots that contain only back vowels choose the back vowel variants of suffix vowels, and conversely, roots that contain only front vowels select the front vowel variants. Representative examples of the simplest cases of harmony are given in Example (1):

(1)

	1PL POSS	ALLATIVE	ADESSIVE	DELATIVE
'house'	ház-unk	ház-hoz	ház-nál	ház-ról
'book'	könyv-ünk	könyv-höz	könyv-nél	könyv-ről
'eye'	szem-ünk	szem-hez	szem-nél	szem-ről

The unrounded front vowels *i*, *í*, *e*, and *é* are commonly referred to as neutral or transparent, though the status of *e* is debated. These vowels are neutral in the sense that in roots they may co-occur freely with back vowels (as well as with front vowels, of course), and they are transparent in that in roots in which they follow a back vowel (as well as when they precede), suffix harmony is determined by the back vowel. Transparent patterning is also evident in suffixal *i*, *í*, and *é*: they are invariably front (i.e., do not alternate harmonically), but nevertheless let backness harmony propagate through them to the next alternating suffix vowel. (Clearly, invariable *é* and harmonic *é* – that is, the front reflex of *á* – must have

different underlying sources: /e:/ and /ɑ:/, respectively.) These properties are apparent in the following examples: *tányér* 'plate', *tányér-hoz* 'to (the) plate', *tányér-jai* 'his plates', and *tányér-jai-hoz* 'to his plates'.

Deviations from the preceding patterns can be grouped into five classes. First, in roots containing a back vowel followed by *e*, *é*, or two or more unrounded front (neutral/transparent) vowels, suffix vowels may vacillate between back and front (e.g., *Ágnes-nak* or *Ágnes-nek* 'to Agnes', *aszpirin-nal* or *aszpirin-nel* 'with aspirin'). As might be expected, there is a good deal of intraspeaker as well as interspeaker variability in these cases. Second, in some roots with a back vowel and a final *e* or *é*, only the front vowel variants are acceptable (e.g., *október-ben* 'in October', *oxigén-nel* 'with oxygen'). Third, in exceptional cases, roots (of foreign origin) may be disharmonic: they contain both front rounded and back vowels. In these words, root harmony is irregular, but suffix harmony is entirely regular: the last harmonic vowel governs harmony in suffixes (e.g., *operatőr-nek* 'to (the) cameraman', *nüansz-unk* 'our nuance'). Fourth, 60 or so almost exclusively monosyllabic roots containing *i* or *í*, less frequently *é*, govern back harmony (e.g., *híd-nál* 'at (the) bridge'). (The expected behavior is front harmonic: cf. *víz-nél* 'at (the) water'.) Fifth, there exist a few invariable suffixes with back vowels; however, the morphology places these suffixes outside the domain of vowel harmony.

Although the facts can only be sketched here, any serious inquiry into the vowel harmony system of Hungarian can but attest to its richness, depth, and complexity. The theoretical issues on which the Hungarian vowel harmony system has proved to have impact in the literature include, among others, the abstractness of phonological representations, the representation of transparency and opacity, the gradience of transparency, adjacency, underspecification, prespecification, monovalent vs. bivalent features, and feature geometry.

Obstruent Voicing Assimilation Obstruent consonants agree in voicing with a following obstruent (across word boundary as well). Examples are *ház* [hɑ:z] 'house', *ház-tól* [hɑ:sto:l] 'from (the) house', and *rész* [re:s] 'part', *rész-ben* [re:zbɛn] 'in part'. The sonorants /m n ɲ l r j/ are neither targets nor triggers. Two phonemes exhibit inconsistent behavior with respect to voicing assimilation: /v/ undergoes assimilation but does not cause it, and /h/ causes assimilation but resists it. This dual patterning of /v/ and /h/ with respect to the obstruent vs. sonorant classification (depending on syllable position) has received due attention in the literature.

Palatalization Dental stops become palatals before palatals (/c ɟ ɲ j/): /t d n/ become /c ɟ ɲ/, respectively (across word boundary as well). An example is seen in *szén* [se:n] 'coal', *gyár* [ɟɑ:r] 'factory', *széngyár* [se:ɲɟɑ:r] 'coal factory'.

Affrication Dental, alveolar, and alveopalatal stop and fricative and affricate sequences undergo an intricate manner of articulation assimilations (some across word boundary as well), resulting in affricates (e.g., *hat* [hɒt] 'six', *szám* [sɑ:m] 'number', *hat szám* [hɒʦʦɑ:m] 'six numbers').

Sibilant Assimilation A sibilant (/s z ʃ ʒ ʧ ʤ ʦ/) assimilates its place of articulation to a following sibilant (across word boundary as well), as in *kis* [kiʃ] 'small', *szamár* [sɒmɑ:r] 'donkey', *kis szamár* [kissɒmɑ:r] 'small donkey'.

Liquid Assimilation An /l/ fully assimilates to a following /r/ or /j/, as in *bal* [bɒl] 'left', *bal-ra* [bɒrrɒ] 'to (the) left)', bal-juk [bɒjjuk] 'their left'.

Nasal Assimilation An /n/ becomes bilabial before bilabials (across word boundary as well). Clearly, this is a larger process that subsumes the allophonic variation of /n/ described in the list of consonants in the first section (Phonemics). An example is seen in *szalon* [sɒlɔn] 'salon', *szalon-ba* [sɒlɔmbɒ] 'into (the) salon'.

/j/-Assimilation Suffix-initial /j/ fully assimilates to a preceding sibilant or palatal consonant, as in *vár* [vɑ:r] 'wait for', *vár-ják* [vɑ:rjɑ:k] 'they wait for it', but *hoz* [hɔz] 'bring', *hoz-zák* [hozzɑ:k] 'they bring it', *hagy* [hɒɟ] 'allow', *hagy-ják* [hɒɟɟɑ:k] 'they allow it'.

Length Alternations

Low Vowel Lengthening The low vowels *a* /ɒ/ and *e* /ɛ/ lengthen to *á* /ɑ:/ and *é* /e:/, respectively, before suffixes (except for two), no matter whether consonant initial or vowel initial; the low vowels stay short in word-final position, as in *kutya* 'dog', *kefe* 'brush'; *kutyá-ja* 'his dog', *kefé-je* 'his brush'; *kutyá-já-val* 'with his dog', *kefé-jé-vel* 'with his brush'; and *kutyá-i* 'his dogs', *kefé-i* 'his brushes'. This is established as a case of lengthening by the fact that all morphemes ending in a low vowel undergo it. The alternative view, shortening, would face a host of exceptions: there exist a good number of roots with final *é*, some with final *á*.

Degemination Geminate consonants become short next to another consonant, both within words and

across, as in *kedd* [kɛdd] 'Tuesday', *kedd-re* [kɛdrɛ] 'to Tuesday', and *kedd reggel* [kɛdrɛggɛl] 'Tuesday morning'. Fake geminates – that is, two identical consonants next to each other but belonging to separate morphemes – evidence the same story, as in *nyelv* [ɲɛlv] 'language', *vizsga* [viʒgɒ] 'examination', *nyelv-vizsga* [ɲɛlviʒgɒ] 'language (proficiency) examination'. Degemination is applied variably (optionally, obligatorily, or not at all), depending on factors such as the phonological constitution of the flanking consonant, speech style, and speech tempo.

Compensatory Lengthening In syllable coda positions, the sonorants /l r j n/ may be elided, generally in casual speech; to compensate for this loss, a preceding short vowel is lengthened. (Long vowels do not become longer as a result of this process.) The most common cases involve /l/; in the case of /n/, its loss is compensated for also by nasalizing the preceding vowel.

Compensatory lengthening is a postlexical, structure-changing process: height adjustment is suspended for nonhigh vowels. Accordingly, /ɛ/, /ɒ/, /ɔ/, and /œ/ lengthen to /ɛ:/, /ɒ:/, /ɔ:/, and /œ:/, respectively, as in *fel* [fɛl] 'up', *felmegy* [fɛ:mɛɟ] 'goes up', *az* [ɒz] 'that', *ar-ra* [ɒrrɒ] or [ɒ:rɒ] 'to that', *bolt* [bɔlt] or [bɔ:t] 'shop', and *zöld* [zœld] or [zœ:d] 'green'. These cases are in sharp contrast with lexical lengthening processes that must preserve distinctive values. Thus, for example, low vowel lengthening turns *a* [ɒ] into [ɑ:] rather than [ɒ:], and *e* [ɛ] into [e:] rather than [ɛ:] (see earlier, Low Vowel Lengthening).

Suffix Vowel Deletion

Suffixes that unquestionably begin with a vowel lose that vowel if appended to a morpheme that ends in a vowel, as in *könyv-ünk* 'our book' and *padló-nk* 'our floor'. Linking vowels, the analysis of which is not straightforward, evidence a similar pattern: cf. *könyv-ek* 'books' and *padló-k* 'floors'.

Suffix Vowel Epenthesis

A low vowel is inserted between verbal stems ending in CC and suffixes that are attached to the stem directly, without an intervening linking vowel. Compare the paradigms of the representative verbs *imád* 'adore' (ending in C) and *áld* 'bless' (ending in CC) in Example (2):

(2)

imád-ni 'to adore'	áld-ani 'to bless'
imád-sz 'you (SG) adore'	áld-asz 'you (SG) bless'
imád-nak 'they adore'	áld-anak 'they bless'
imád-na 'he would adore'	áld-ana 'he would bless'
imád-lak 'I adore you'	áld-alak 'I bless you'

Some stems resist low vowel epenthesis, whereas others allow it optionally.

Nongeneral Processes

/v/-Assimilation The initial consonant of the instrumental suffix *-val/vel* and of the translative suffix *-vá/vé* fully assimilates to a preceding consonant, as in *hajó* [hɒjo:] 'ship', *hajó-val* [hɒjo:vɒl] 'with ship', but *öröm* [œrœm] 'joy', *öröm-mel* [œrœmmɛl] 'with joy'.

/z/-Assimilation In the demonstrative pronouns *ez* 'this' and *az* 'that', the final /z/ fully assimilates to the consonant of a following CV-initial suffix, as in *idő* [idø:] 'time', *idő-ben* [idø:bɛn] 'in time', but *ez* [ɛz] 'this', *eb-ben* [ɛbbɛn] 'in this'.

/t/-Palatalization If the imperative suffix *-j* is appended to a verb ending in /t/, then /t/ palatalizes to /ʃ/ if preceded by a vowel and to /ʧ/ if preceded by a sonorant consonant (/t/ deletes if preceded by an obstruent consonant; see later, /t/-Deletion). An example is seen in *vár* [vɑ:r] 'wait', *vár-j* [vɑ:rj] 'wait!', but *üt* [yt] 'hit', *üs-s* [yʃʃ] 'hit!', *önt* [œnt] 'pour', *önt-s* [œnʧʧ] (or [œnʧ], reflecting the effect of degemination) 'pour!'. Once the /t/ palatalizes to the sibilant /ʃ/ or /ʧ/, /j/ fully assimilates to it by the process mentioned in the discussion of /j/-Assimilation. Seven underived verbal stems (roots) plus all stems derived by the causative suffix *-ít*, all of which end in a long vowel plus /t/, consistently pattern with verb stems that end in a consonant cluster. (Three verbal roots ending in a long vowel plus /t/ pattern with verbs ending in a vowel plus /t/.) Thus, for instance, the verb *fűt* 'heat' palatalizes its /t/ to [ʧ] (cf. *fűts* [fy:ʧʧ] 'heat!'), just like *önt*, and induces suffix vowel epenthesis (cf. *fűt-eni* 'to heat'), just like *áld*. Both of these facts fall out if, in verbs such as *fűt*, the long vowel is analyzed as VC, as was suggested in Vago (1980).

Metathesis Metathesis is observed in three roots, ending in clusters containing /h/ plus either /r/ or /j/. Word finally and before consonant-initial suffixes, the sequence /hr/ or /hj/ appears, broken up by a vowel (see later, Stem Vowel Syncope/Epenthesis), but before vowel-initial suffixes, /rh/ or /jh/ shows up (recall that orthographic *ly* = [j]):

(3)

	NOMINATIVE	DATIVE	PLURAL
'chalice'	kehely	kehely-nek	kelyh-ek
'fluff'	pehely	pehely-nek	pelyh-ek
'load/weight'	teher	teher-nek	terh-ek

/h/-Deletion About 10 nominal roots end in /h/ before vowel-initial suffixes. Otherwise, i.e., word finally and before consonant-initial suffixes, /h/ deletes

(regardless of whether the next word begins with a vowel or a consonant). An example is seen in *cseh* [ʧɛ] 'Czech', *cseh-nek* [ʧɛnɛk] 'to (the) Czech)', *cseh-ek* [ʧɛɦɛk] 'Czechs', *Csehország* [ʧɛɔrsɑ:g] 'Czech Republic', and *cseh katona* [ʧɛkɒtɔnɒ] 'Czech soldier'. Counterexamples abound, where /h/ is not deleted; in these cases, syllable-final /h/ is pronounced as velar [x] after back vowels, and as fronted-velar or palatal [ç] after front vowels, as in *doh* [dɔx] 'musty smell', *doh-tól* [dɔxto:l] 'from (the) musty smell', and *doh-os* [dɔɦɔʃ] 'musty'. Furthermore, roots that delete their final /h/ are unstable in that they develop variants that either optionally or obligatorily retain /h/. Since the glottal and velar variants (ignoring the fronted version of the velar) never contrast, it is possible to set up either one as the basic phoneme.

Stem Vowel Syncope/Epenthesis In several hundred historically old nominal and verbal roots, as well as in a few nominal derivational suffixes, a short mid vowel (adjusted for vowel harmony) appears between the last two consonants if these morphemes are word final or are followed by a consonant-initial suffix; if followed by a vowel-initial suffix, the short mid vowel is absent. An example is seen in *ökör* 'ox,' *ökör-rel* 'with ox', and *ökr-ünk* 'our ox'. These alternations have been analyzed in terms of both deletion and insertion; however, it is not possible to account for the facts in purely phonological terms.

Root Vowel Lowering In less than two dozen nominal stems, a final mid rounded vowel is lowered before suffixes beginning with /i/ or /j/, as seen in Example (4):

(4)

	NOMINATIVE	DATIVE	3PL POSS
'door'	ajtó	ajtó-nak	ajta-ja
'forest'	erdő	erdő-nek	erde-je

This process is unproductive, applying to a closed set of historically old nouns.

Root Vowel Deletion A vowel in root-final position is lost before vowel-initial derivational suffixes, as in *hülye* 'silly', *hülyé-sked(-ik)* 'act(s) silly' (derivation), *hülyé-i-nk* 'our fools' (inflection), *hülyé-nek* 'to (the) fool' (inflection), but *hüly-ül* 'becomes (a) fool' (derivation). Also, in about 10 nominal and adjectival roots, a final long high rounded vowel deletes before vowel-initial suffixes, as in *borjú* 'calf', *borjú-val* 'with (the) calf', but *borj-ak* 'calves'.

Root Vowel Length Alternation In nearly 100 roots, all monosyllabic or bisyllabic, ending in a single consonant, the final syllable has a long vowel, if that syllable is word final or is followed by a consonant-initial suffix; the final syllable has a short vowel before a (derivational or inflectional) vowel-initial suffix. An example is seen in *kéz* 'hand', *kéz-ben* 'in hand', and *kez-ünk* 'our hand'. This process is restricted to a closed set of roots. In verbs, most of the alternating vowels are high, but in nouns, they are mainly *e/é* or *a/á*.

Root Internal Vowel Shortening In a large set of roots (on the whole, borrowed words), a long vowel, no matter in what syllable, becomes short before suffixes that have the following characteristics: they are derivational, vowel initial, bisyllabic, and invariant with respect to vowel harmony. An example is seen in *miniatűr* 'miniature', *miniatür-izál* 'miniaturize'.

Root-Final /v/-Alternation In a little over 20 roots, the final segment is vocalized as a high or mid rounded vowel word finally and before consonant-initial suffixes; /v/ shows up before vowel-initial suffixes. The following three patterns are observed:

(5)

	NOMINATIVE	DATIVE	PLURAL
'village'	falu	falu-nak	falv-ak
'pipe'	cső	cső-nek	csöv-ek
'word'	szó	szó-nak	szav-ak

/t/-Deletion Verb stems that end in an obstruent consonant plus /t/ lose their final consonant before the imperative morpheme /j/. Thus, for example, when *fest* [fɛʃt] is concatenated with the imperative suffix /j/ (cf. *kér* 'ask', *kér-j* 'ask!'), first /t/ drops out and then /j/ fully assimilates to the preceding strident /ʃ/ (cf. /j/-Assimilation); the output is *fess* [fɛʃʃ] 'paint!'.

Suprasegmentals

Stress

Hungarian words receive primary stress on the initial syllable (except in cases involving function words, rhythmic stress, and contrastive stress); the existence of secondary stress at the lexical level has been the subject of debate. Lexical initial stress may be absent (or reduced to secondary stress) in the higher level patterns of sentential stress (influenced by syntactic structure), due, in particular, to enclisis and stress eradication.

Intonation

Hungarian words have the following major intonational patterns: (1) steady pitch, when the syntax or

pragmatics has an implicational function, (2) initial falling pitch, used primarily for questions containing interrogative pronouns (*wh*-questions), exclamations, imperatives, and declaratives, and (3) final falling pitch, used in the case of all other question types. On the whole, the intonational peak occurs in the initial syllable of the prosodic domain; in some cases (e.g., yes/no questions), it occurs in the penultimate syllable.

Emphasis and Contrast

Emphatic and contrastive elements must be in focus position syntactically. They are followed by falling intonation, due to the facts that the stressed initial syllable of the emphasized or contrasted word receives high pitch and that all subsequent primary stresses in the phrase are destressed (eradicated).

Hungary: Language Situation

M Kontra, Hungarian Academy of Sciences, Budapest, Hungary

© 2006 Elsevier Ltd. All rights reserved.

The Treaty of Trianon after World War I reduced the size and population of Hungary by about two-thirds, divesting it of virtually all areas that were not purely Magyar. After 1920, Hungary, once a multiethnic and multilingual kingdom, became a fairly homogeneous country in linguistic terms. Census data from 2001 show that 98.5% of 10.2 million people in Hungary claimed Hungarian as their mother tongue. (With about 3 million native speakers in the seven neighboring countries, Hungarian is a pluricentric language.)

According to the 2001 census, Armenian was claimed as mother tongue by 294 people, Bulgarian by 1299, Croatian by 14 345, German by 33 792, Greek by 1921, Gypsy (i.e., Romany and Boyash, an archaic dialect of Rumanian, collapsed in a linguistic fashion by the Hungarian Statistical Office) by 48 685, Polish by 2580, Rumanian (Romanian) by 8482, Ruthenian (Rusyn) by 1113, Serbian by 3388, Slovak by 11 816, Slovene (Slovenian) by 3187, and

pragmatics has an implicational function, (2) initial falling pitch, used primarily for questions containing interrogative pronouns (*wh*-questions), exclamations, imperatives, and declaratives, and (3) final falling pitch, used in the case of all other question types. On the whole, the intonational peak occurs in the initial syllable of the prosodic domain; in some cases (e.g., yes/no questions), it occurs in the penultimate syllable.

The Treaty of Trianon after World War I reduced the size and population of Hungary by about two-thirds, divesting it of virtually all areas that were not purely Magyar. After 1920, Hungary, once a multiethnic and multilingual kingdom, became a fairly homogeneous country in linguistic terms. Census data from 2001 show that 98.5% of 10.2 million people in Hungary claimed Hungarian as their mother tongue. (With about 3 million native speakers in the seven neighboring countries, Hungarian is a pluricentric language.)

According to the 2001 census, Armenian was claimed as mother tongue by 294 people, Bulgarian by 1299, Croatian by 14 345, German by 33 792, Greek by 1921, Gypsy (i.e., Romany and Boyash, an archaic dialect of Rumanian, collapsed in a linguistic fashion by the Hungarian Statistical Office) by 48 685, Polish by 2580, Rumanian (Romanian) by 8482, Ruthenian (Rusyn) by 1113, Serbian by 3388, Slovak by 11 816, Slovene (Slovenian) by 3187, and

Ukrainian by 4 885 speakers. Compared with the 1990 census, some minorities are stable (Bulgarians, Gypsies, Rumanians), others have decreased (Croatians, Germans, Poles), while others have increased (Greeks, Serbs, Slovenes, Ukrainians). Over 135 000 people claimed a language other than Hungarian as their mother tongue, over 166 000 claimed they used such a language in their home, and over 314 000 claimed they belonged to a national or ethni minority. An estimated 30 000 Hungarians are deaf and another 300 000 are hard of hearing. The use of Hungarian Sign Language in deaf schools is barely tolerated. Minority languages, where and when spoken, are typically restricted to the home or to private conversations between friends. Under the Minorities Act of 1993, mother-tongue-medium education must be provided for minority children in a locality if at least eight children's parents demand it.

The national and ethnic minorities live dispersed among Hungarians in various parts of the country. Whereas Hungarians and Slovenes are autochthonous to Hungary, Croats, Serbs, and Rumanians settled in Hungary before or during the Ottoman Turkish occupation of the country in the 16th and 17th centuries. The majority of the Germans and Slovaks were settled in the newly liberated territories after the Ottoman Turks were driven out of the country in 1686. Gypsies have lived in Hungary since the 15th century.

The Hungarian language community in Hungary is a normatively oriented one with a strong tradition of stigmatizing nonstandard varieties and glorifying standard Hungarian as codified by purists associated with the Hungarian Academy of Sciences. In some respects, language cultivators and schoolteachers are aiming to change the speechways and the notions of correct speech of more than half the population of Hungary.

Husserl, Edmund (1859–1938)

K Willems, University of Ghent, Ghent, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Edmund Husserl is the founder of modern 'phenomenology' (not to be confused with the philosophy of G. F. Hegel, who used the same term) and as such influenced many scholars, among them M. Heidegger, J.-P. Sartre, M. Merleau-Ponty, M. Scheler, E. Levinas, J. Derrida, and E. Coseriu. Husserl was born into a family of German-speaking Jews in the Moravian town of Prossnitz, then part of the Austrian Empire, now Prostějov in the Czech Republic. He moved to Leipzig in 1876 to study mathematics, physics, astronomy, and philosophy. He continued his studies in Berlin (1878–1881) and in Vienna, where he received his doctoral degree in 1883, at the age of 24. After attending Franz Brentano's lectures in philosophy in Vienna, Husserl moved to Halle, where he converted to Protestantism in 1886. In Halle he wrote his *Habilitation* thesis *Über den Begriff der Zahl* (1887) under Carl Stumpf, a student of Brentano, and became *Privatdozent* (1887–1901). His first published book, *Philosophie der Arithmetik. Psychologische und logische Untersuchungen* (1891), was based on that thesis and deals with the foundations of mathematics. Because of its psychologism, the book was reviewed very critically by Gottlob Frege. A decade later, Husserl himself was to refute psychologism in logic and philosophy once and for all in his influential *Logische Untersuchungen* (1900–1901). He became associate professor (1901–1906) and then professor (1906–1916) of philosophy at the University of Göttingen and eventually succeeded Heinrich Rickert as professor of philosophy at the University of Freiburg im Breisgau (1916–1928). He

Edmund Husserl is the founder of modern 'phenomenology' (not to be confused with the philosophy of G. F. Hegel, who used the same term) and as such influenced many scholars, among them M. Heidegger, J.-P. Sartre, M. Merleau-Ponty, M. Scheler, E. Levinas, J. Derrida, and E. Coseriu. Husserl was born into a family of German-speaking Jews in the Moravian town of Prossnitz, then part of the Austrian Empire, now Prostějov in the Czech Republic. He moved to Leipzig in 1876 to study mathematics, physics, astronomy, and philosophy. He continued his studies in Berlin (1878–1881) and in Vienna, where he received his doctoral degree in 1883, at the age of 24. After attending Franz Brentano's lectures in philosophy in Vienna, Husserl moved to Halle, where he converted to Protestantism in 1886. In Halle he wrote his *Habilitation* thesis *Über den Begriff der Zahl* (1887) under Carl Stumpf, a student of Brentano, and became *Privatdozent* (1887–1901). His first published book, *Philosophie der Arithmetik. Psychologische und logische Untersuchungen* (1891), was based on that thesis and deals with the foundations of mathematics. Because of its psychologism, the book was reviewed very critically by Gottlob Frege. A decade later, Husserl himself was to refute psychologism in logic and philosophy once and for all in his influential *Logische Untersuchungen* (1900–1901). He became associate professor (1901–1906) and then professor (1906–1916) of philosophy at the University of Göttingen and eventually succeeded Heinrich Rickert as professor of philosophy at the University of Freiburg im Breisgau (1916–1928). He

died in Freiburg in 1938. Husserl lost a son at Verdun during World War I; his second son, Gerhart Husserl, became a respected philosopher of law.

Although several of Husserl's manuscripts were published during his lifetime, often with the aid of assistants such as E. Stein, M. Heidegger, and E. Fink, most of his texts were published posthumously. After the publication of the *Logische Untersuchungen*, Husserl produced approximately 40 000 pages of shorthand manuscripts, which were rescued and transferred to Leuven (Belgium) shortly after his death, before the Nazis could confiscate and destroy them. (Today, there are Husserl Archives in Leuven, Freiburg, Cologne, New York, Paris, and Duquesne/Pittsburgh.) The manuscripts have been transcribed for publication since 1950 in the so-called *Husserliana* edition. They show that Husserl's thought evolved through various stages. From a philosophical and psychological account of the foundations of mathematics in the 1880s, he proceeded to a detailed elucidation of 'natural logic' and cognitive processes such as expressing thoughts, intentionality, abstraction, etc., around the turn of the century. During the first decades of the 20th century, Husserl's thinking broadened to encompass many important methodological issues, including the differences between realism and idealism, time consciousness, the genesis of logical categories out of everyday life experience, transcendental (Kantian) philosophy, and the relation between the individual and the community. Most texts of this later period were published only posthumously. The ambition grew in Husserl to present phenomenology as a general perspective from which all important philosophical problems could in principle be tackled. Finally, in the last stage of the development of his thought, Husserl set out to write a comprehensive critique of the pervasive objectivism and scientism he detected in the history of the sciences since Galilei, arguing that all scientific reasoning is founded – indeed necessarily rooted – in the human 'life world' (*Lebenswelt*).

Husserl's influence on 20th-century Western thought can hardly be overestimated. The primary reason for his lasting influence is the great variety of philosophical, epistemological, and logico-linguistic analyses that go hand in hand in Husserl's phenomenology. In addition, Husserl's work was and continues to be an impressive rebuttal of all kinds of amateurish philosophy. His credo that philosophy should be a 'rigorous science' ('Philosophie als strenge Wissenschaft' is the title of one of his most famous articles) still stands as a barrier to unfounded speculation, confused ideological reasoning, and superficial pseudophilosophy. If one looks at the more than 30 volumes by now published in the *Husserliana* edition, one is struck by the scope and breadth of Husserl's thought. Although many of his writings have, with hindsight, the character of introductions or preliminary assessments of particular topics and problems, together they constitute one of the most convincing modern syntheses of the theoretical rigor of the transcendental and idealistic tradition of German philosophy on the one hand, and an intellectual realism firmly rooted in empirical investigations of the mind and the foundations of human knowledge on the other. Husserlian phenomenology is above all an intellectual attitude, a way of 'doing philosophy' and of 'looking' at the world and the way human beings experience that world (the 'phenomena'). Its aim is to describe the conditions of common sense as well as scientific knowledge. To this end Husserl unravels the multiple relations between what is constituted through the activity of the mind and the ways the objects of knowledge present themselves through experience, thus accounting for what is rendered evident through the phenomena themselves (hence Husserl's famous call *Zu den Sachen selbst!* 'to the things themselves!'). In such a project, signs and processes of signification obviously play an important role, and Husserl must be credited with developing a thought-provoking theory of meaning that does justice not only to intentionality in general but also to some of the essential features of natural language and linguistic meaning.

Phenomenology can serve as an epistemological framework for all kinds of research within the field of the humanities, linguistics being no exception. Husserl's contribution to the philosophy of language and linguistic theory is unmistakable. Moreover, some of his findings in the phenomenology of meaning are still valuable. The central phenomenological concept is intentionality. For Husserl, consciousness is not a state of the mind but a dynamic attitude that always implies a 'directedness' toward some object(s) or state of affairs. In focusing on intentionality, the phenomenologist abstracts away from the accidental features of the phenomena he is considering and seizes what is essential to them (*Wesensschau*). This can be achieved, according to Husserl, by intuiting the objects **as** objects, i.e., as immanent parts of the intentional focus itself ('intuitive givenness'). Phenomenological 'reductions' of this kind have a number of remarkable consequences when applied to linguistics.

First of all, everyday language use is unveiled as being only a component part of complex cognitive and communicative processes in cultural contexts. In actual life, language is not given as a bare phenomenon but interwoven with acts of reference, knowledge of the world and culture, customs,

attitudes toward other speakers, associations, etc. Therefore, the study of language necessarily presupposes a reductive abstraction through which language proper can be distinguished from the innumerable concomitant aspects of language use; together all these aspects form the highly complex preliminary knowledge all language science is based upon.

Secondly, from a Husserlian perspective, meanings are to be distinguished from their (potentially infinite) instantiations in referential contexts because, unlike the latter, meanings are 'essences' or 'species.' Whenever a meaning is instantiated in a particular act of language use, the meaning itself is not present to the mind because consciousness is then focused on the object(s) or state of affairs referred to. Meaning is the necessary condition of the act of reference (cf. **Kant, Immanuel (1724–1804); Coseriu, Eugenio (1921–2002)**). On the other hand, it is irrelevant whether a particular object really exists or is a mere object of thought. As Husserl argues in the famous 'First investigation,' 'Expression and meaning' ('*Ausdruck und Bedeutung*') of his *Logische Untersuchungen*, "the object never coincides with the meaning." Conversely, entirely different 'ideal' meanings can be used to refer to one and the same object or state of affairs. Telling examples are *the victor of Jena* and *the vanquished at Waterloo* (both refer to Napoleon) or *a is larger than b* and *b is smaller than a*. There is one exception to the rule that meaning and reference do not coincide, though. This exception is, according to Husserl, the proper name. The meanings of appellative nouns (e.g., *horse* and *man*) are classematic, i.e., they designate classes and hence are potentially universal. Proper names, on the other hand, although also meaningful, are used to refer in a 'direct' way, not via lexical meaning. This means that whereas appellatives have a vast extension, proper names have only one extension, which is identical with their intension in a given speech act. Still, proper names can be equivocal because they can share one and the same form with other names (or words).

Husserl also emphasizes that not everything that a native speaker of a language interprets as absurd or nonsensical is actually meaningless. There is a clear distinction between ill-formed expressions that are indeed meaningless, like *a round or* or *a human being and is*, and expressions to which no object(s) or state of affairs are known to correspond but which nevertheless have a homogenous 'ideal' meaning, e.g., *a round square* and *all rectangles have 5 angles*. Such examples not only prove that meaning combinations in the Husserlian sense can be homogenous only if the individual meanings of the parts of an expression are compatible with one another; they also show that the objectivity of some intended meaning, and thus ultimately the truth of an expression (i.e., an utterance expressed on a particular occasion and intentionally directed toward one or more objects or states of affairs), depends on the phenomena in the world and cannot possibly be rendered by linguistic signs and significations alone (cf. **Plato and His Predecessors**).

Whenever Husserl talks about 'grammar,' 'expression,' 'meaning,' etc., he is dealing with abstractions, and he consistently refers to aspects of language in general, not to any actual language(s). Not surprisingly, Husserl was particularly sensitive to R. Descartes's and G. W. Leibniz's doctrines of a *characteristica universalis*, which Husserl partly tried to revive in his outline of a theory of 'pure grammar' (*Logische Untersuchungen*). There, Husserl is not so much concerned with what today's grammarians mean by 'grammar' (including 'syntax' and 'semantics') as with the structures of logical reasoning and their genesis in experience and consciousness, e.g., the structure of judgments of the form *S is p*, the difference between simple and complex meanings (*man* vs. *a man of iron*), etc. Crucially, however, such laws of logic can be assessed adequately only after one has tried to understand what 'meaning,' 'expression,' 'sentence,' etc., mean with regard to the signs of natural language.

Definition

The term 'hymn,' from Greek *húmnos*, means, in the broadest sense, 'song of praise,' directed especially to a deity. This type of song, which is connected to religious worship and responds to man's need to communicate with the divine, is typical of all cultures and later assumes a literary form. The most ancient hymns are Vedic, Sumerian-Babylonian, and Egyptian, dating from *ca*. 2000 B.C., followed chronologically by Greek, Latin and, related to the latter, though not exclusively, Christian hymns, which have continued down to the present time. In spite of the presence and importance of hymns in pagan culture, it is, without doubt, in Christianity that they occupy the most prominent place.

The object of the hymn, the deity (directly or indirectly), demands that the style of the composition be appropriate, in that the language used should be solemn and in verse, above all metrical, but also rhythmical. There are compositions with these characteristics, in prose, which pose the question of whether they can be truly considered hymns.

The structure of the hymns is generally tripartite: (1) invocation of the deity, often elaborated on by epithets; (2) praise of the deity; (3) concluding statement, accompanied by thanksgiving or petitioning of the deity. Christian hymns add a fourth part, the doxology or glorification of the Holy Trinity. In the case of Christian hymnody, the praise of the divinity can be done indirectly, that is, in hymns dedicated to the Virgin, saints and martyrs, divine mysteries, ecclesiastic feasts, and so on. In the study of structure, and especially of the religious language of hymns and prayers, the work of Norden (1913) remains fundamental. A comprehensive overview of pagan and Christian hymns can be found in the work of Lattke (1991).

Pagan Hymns

Greek literature offers a rich and varied selection of 'songs in praise of the gods and heroes.' These were composed in varying metrical versification, especially lyrical, and were often accompanied by musical instruments, such as the kithar or the aulos, by dancing, and with alternating modulation being predominant. However, not all were sung or composed in verse form. The most outstanding examples of Greek hymns are the Homeric Hymns; the lyrical hymns (e.g., the paean, a song to Apollo and the dithyramb, a song to Dionysus); the triumphal odes by authors such as Pindar; the hymns of Calimachus, or the Orphic Hymns.

In Latin literature, real hymns are rare; however, the role of Horace in subsequent hymnody would prove to be of great importance.

Christian Hymns

Early Christian 'Hymns'

Christian 'hymns' begin with the foundation of the Church. Early Christian communities, in their religious celebrations, sang their praises, following the Jewish tradition. These consisted mainly of psalms and canticles of the Old Testament (e.g., Vulg. Deut. 32: 1–43; Judges 5: 2–31; Judith 16: 2–21) and from the New Testament (e.g., Vulg. Luke. 1: 46–55; 1: 68–79; and 2: 29–32), to which the early Christians added, in the 2nd and 3rd centuries A.D., new hymns, based on Holy Scripture. For the most part, they were written in the Greek language, in prose, but

In Latin literature, real hymns are rare; however, the role of Horace in subsequent hymnody would prove to be of great importance.

Christian Hymns

Early Christian 'Hymns'

Christian 'hymns' begin with the foundation of the Church. Early Christian communities, in their religious celebrations, sang their praises, following the Jewish tradition. These consisted mainly of psalms and canticles of the Old Testament (e.g., Vulg. Deut. 32: 1–43; Judges 5: 2–31; Judith 16: 2–21) and from the New Testament (e.g., Vulg. Luke. 1: 46–55; 1: 68–79; and 2: 29–32), to which the early Christians added, in the 2nd and 3rd centuries A.D., new hymns, based on Holy Scripture. For the most part, they were written in the Greek language, in prose, but

of these little remains; some surviving examples are '*Dóksa en hupsístois*' (in Latin: '*Gloria in excelsis*'), '*Triságion*' and '*Phôs Hilarón*.'

Christian Hymns

Christian hymns, as such, appear in the 4th century A.D. with the twin aims of doctrine and apologetics, to defend the Christian faith from heresy. The precursor was St. Ephrem, in the East, who wrote hymns in Syriac; his example was followed by Gregory of Nazianzus (in Greek) and, in the West, by St. Hilary of Poitiers and St. Ambrose, the father of the Latin hymnody. These hymns were composed in stanzas, in the style of pagan poetry, and were sung in churches by the congregation. In the 4th century A.D., Prudentius composed hymns but with a different aim; his two collections of hymns (*Cathemerinon*, for the daily rounds, and *Peristephanon*, to the martyrs) were aimed at a select, learned public and are of a meditative nature.

From this time and throughout the Middle Ages, new writers appear who base their hymns on these models, but who also introduce new styles and content, ever enriching the hymnody. St. Augustine's definition of hymn (4th century: *Cantus est cum laude Dei* 'Song in praise of God'), which was valid at one time, must necessarily be broadened.

At first, these hymns were metrical, in verses, as in pagan poetry (especially iambic dimeter, the most popular, Sapphic stanza, trochaic and asclepiadic meter), but this slowly gave way to rhythmical poetry, which became the predominant form in the Middle Ages.

Hymns soon formed part of church liturgy in the Episcopalian churches of the East, as in monastic services in the West, where they were sung in antiphony during the daily liturgical hours by two choirs (*modulatio alternans*).

The majority of mediaeval Latin hymns are liturgical, some form part of Divine Office and others of the liturgy of the Mass. But there are also non-liturgical hymns such as those intended for personal meditation. This diverse and numerous body of hymns is collected in the fundamental work *Analecta Hymnica Medii Aevi*, by the Jesuits Dreves and Blume (1886–1922).

Some Latin hymnographers worthy of mention, not included *supra*, are Sedulius, Ennodius, Venantius Fortunatus, The Venerable Bede, Hrabanus Maurus, Notker Balbulus, Peter Abelard, Adam of St. Victor, or St. Thomas Aquinas.

During the Renaissance, the Humanists attempted to 'refine' the mediaeval rhythmical structure of hymns and to adapt them to the new Humanistic parameters, based on classical Latin (classical meters and elegant vocabulary *-latinitas-*), as well as composing new hymns. The contribution to hymnody brought about by, on the one hand, the Lutheran reform, and on the other, the Jesuits, must also be mentioned. With regard to the Roman Breviary, the reform carried out by Pope Urban VIII in 1632 was of great importance. In contrast to this reform, the Second Vatican Council (S.C. 93) determined to return the hymns of the Roman Breviary to their original form (cf. Lentini, 1968).

The tradition of Christian hymns continues to this day, especially in liturgical celebrations, and is common to all denominations.

Hyponymy and Hyperonymy

M L Murphy, University of Sussex, Brighton, UK

© 2006 Elsevier Ltd. All rights reserved.

Hyponymy is the 'type of' relation among lexical items; for example *rose* is a hyponym of *flower* in that roses are types of flowers. In other words, if X is a hyponym of Y, then the extension of X is a subset of the extension of Y. Thus, we can say that hyponymy is a relation of inclusion. Its converse is hyperonymy (also called *hypernymy* or *superordinacy*); *flower* is the hyperonym (or superordinate) of *rose*. The term *hyponymy* is also used generally to refer to the relation that holds between a hyponym and hyperonym. While this relation is central to many theories of lexical organization, it is arguably not a lexical relation at all but instead a semantic relation that reflects the relations among the things words designate. Nevertheless, it is a central relation (along with incompatibility) in many theories of lexical organization. We can use an angle bracket (>) to indicate this relation between two expressions (e.g., *flower* > *rose*).

Hyponymy as a Paradigmatic Relation

Hyponym relations can be represented in tree structures, as in the abbreviated FRUIT taxonomy in Figure 1. The items in this tree can be considered to be parts of a hyponymic (or taxonomic) paradigm.

Note that the tree (and the relation itself) is asymmetrical, in that any word may have many hyponyms, but in most cases has only one immediate hyperonym. For example, *orange* has several hyponyms (*navel, Valencia, mandarin*), but each of these has only one hyperonym (*orange*), and it has only one immediate hyperonym (*citrus*), and so forth. Lyons notes (Lyons, 1977) that for some syntactic categories, hyperonyms are often of a different syntactic category than the hyponyms. For example, adjectives may have nominal hyperonyms, as in *emotion* > {*happy, sad, angry*}. Because hyponymy is considered to be a paradigmatic relation, and paradigmatic relations are generally defined as holding between members of the same syntactic category: Lyons dubs these cross-categorical relations *quasi-hyponymy*. But even in nominal taxonomies, we see some differences in syntactic categories at the highest levels. In Figure 1, while *citrus* can be used as a noun, it is more often used as an adjective (*citrus fruit*), as are the orange types (*navel, mandarin*) at the bottom extreme. And unlike the countable items at the basic level (*an apple, a pear*), *fruit* is in a non-count noun subcategory (*some fruit, a piece of fruit*). Such facts (in an otherwise straightforward taxonomy) raise the question of whether so-called hyponymy is the norm and thus challenge the notions that paradigmatic relations exist within specific syntactic categories and that hyponymy is a paradigmatic relation.

Figure 1 Hyponym relations in the FRUIT lexical field.

Another problem in defining and diagnosing hyponymy is that the natural language diagnostic 'X is a type of Y' is often in conflict with the set inclusion definition. For example, (1) is an odd statement, even though it is indisputable that the set of queens (in the 'monarch' sense of *queen*) is a subset of the set of women.

(1) ?A queen is a type of woman.

To get around these problems of definition, Cruse proposes that HYPONYM is a prototype-based category (Cruse, 2002). Taxonyms, hyponyms that felicitously occur in *type of* statements with their hyperonyms, are among the most prototypical cases of hyponymy in that they participate in entailment relations, and the extra specificity of the hyponym in relation to the hyperonym is central to the meaning of the hyponym. Other features of prototypical hyponym relations (such as *dog* > *terrier*) are directness of the relation (as opposed to *animal* > *terrier*, in which intervening levels have been elided) and sameness of non-denotative aspects of meaning/communicative function, such as register (i.e., as opposed to *pooch* > *terrier*). Such an approach accounts for the perception that some superordinate/subordinate relations are better examples of hyponymy than others.

Types and Properties of Hyponyms

Hyponymy, or at least taxonymy, is transitive, in that if X < Y and Y < Z, then X < Z. Such entailment relations contribute to classical syllogisms, as in (2):

(2) A terrier is a type of dog.
A dog is a type of animal.
∴ A terrier is a type of animal.

However, some items that pass the 'type of' diagnostic for hyponymy do not result in valid syllogisms, as in (3):

(3) A game console is a type of computer.
A computer is a type of office equipment.
A game console is a type of office equipment.

There are two problems with the second premise of (3) that result in the failure of the syllogism. First, the statement is only true when we interpret *a computer* as 'a (proto)typical computer'. So, *computer* in the second premise is defined using different criteria than in the first premise. The other problem here is that the *type of* relations in the two premises are not equivalent. The first premise tells us what a game console *is*, while the second one tells us what a computer *is used for*. While the first premise expresses taxonomic hyponymy (or *taxonymy*), the second is a case of functional hyponymy. Any term might have hyp(er)onyms of both types. For example, a dog can be both an animal (taxonomy) and a pet (function). The entailment relations in syllogisms are only reliably found with taxonomic hyponyms.

Hyponymy and Lexical Organization

Models of the lexicon often involve organization by semantic relation, as in network models (e.g., WordNet, Fellbaum, 1998) and semantic field theory (Lehrer, 1974). In such models, hyponymy is a key organizer of lexical items. The question arises, however, whether these relations are really relations among words (and hence should be represented in a modular lexicon) or if they are just relations among the meanings of the words or among the things that the words describe. Because hyponymy is most often defined as a relation of set inclusion, and because the sets involved are the extensions of the words, not the words themselves or their meanings (intensions), the necessity of representing hyponymy in the lexicon is called into question (Murphy, 2003). Instead, it could be said that the semantic relation of hyponymy is simply a linguistic reflex of the extensional relation of class inclusion. In this case, representing such information as lexical (i.e., specifically linguistic) information is redundant, as the information will already be available as part of our world knowledge. (This contrasts with the more arguably lexical relations of antonymy and synonymy.) Cruse's prototype-based approach above takes into account lexical issues (e.g., similarity of register) as well as the semantic issues. This is useful in metalinguistic discussions of'what's a good example of hyponymy', but again does not require direct representation in a lexicon because the relation between any two words is then derivable from the prototype model. Nevertheless, representation of hyponymy is useful in computational lexicons (such as WordNet) because the aim in these cases is to represent the knowledge base (including semantic relations) that makes using the lexicon meaningful.

Like computational lexicons, dictionaries rely heavily on hyponymy. The typical *genus-differentiae* structure of dictionary definitions involves giving a hyperonym (*genus*) of the defined word, then the means to differentiate the defined word from the set of hyponyms of that hyperonym. For example, *apple* might be defined as 'a (type of) fruit [*genus*], grown on a tree of the rose family, that is typically round and fleshy with thin red, yellow, or green skin [*differentiae*]'. Theories of lexical meaning that follow the model of dictionaries (i.e., in using semantic features or components, e.g., Katz, 1972) similarly give more detail in the representation of the meanings of hyponyms than in the representation of their hyperonyms. So, for example, the semantic representation of *apple* must access (either by inheritance or direct representation) all of the information in the semantic representation of *fruit*. In other words, the meaning of *apple* is the meaning of *fruit* plus some *differentiae*. However Wierzbicka (Wierzbicka, 1984) opposes this position, arguing that the meaning of *fruit* is more complex than that of *apple*. In her view, the word *fruit* does not (unlike *apple*) stand for 'a type of thing', but rather stands for a group of dissimilar types of thing. Therefore she argues that the meaning of *fruit* should encompass the meaning of *apple* (and *orange* and *banana*) rather than *vice versa*. See Bolinger (1992) for counterarguments to this position.

In conclusion, there's no doubt that class inclusion relations are central to cognitive processes such as categorization and reasoning. We use hyponym and hyperonym relations in defining words, and they are useful in creating coherence in discourse without repetition (so, we can refer to the same being as *Fido, the puppy, the dog, the terrier, the animal,* and so forth), and hyponyms and hyperonyms prompt each other in word association tests. Nevertheless, there is not clear evidence that the relation is a linguistic (lexical) relation rather than a cognitive-semantic relation (which reflects relations between referents). Still, the

class inclusion relation (if not the lexical relation of hyponymy) is central to most approaches to lexical semantic representation.

Iartseva, Victoria Nikolaevna (1906–1999)

I A Sizova, Institute of Linguistics, Moscow, Russia

© 2006 Elsevier Ltd. All rights reserved.

Iartseva (Figure 1) was born on November 3, 1906, in St. Petersburg, in the family of a mine engineer. In 1933, she graduated from the Leningrad pedagogical institute with a diploma for English teachers and took a postgraduate course at the Language and Thinking Institute (later on the Institute of Linguistics). There she studied languages of different genetic groups and got a thorough theoretical education under such outstanding scholars as V. M. Žirmunski, I. I. Meshchaninov, and L. V. Shcherba. Three years later, she received her candidate's degree for the thesis 'The development of complex sentences in English.' In 1940, she obtained a doctor's degree ('The development of the English verb') and became a scientific worker at the Institute. For many years, she headed the Department of Germanic Languages (1954–1988) and held the post of Director of the Institute (1968–1977). In 1968, she was elected Corresponding Member of the USSR Academy of Sciences.

Figure 1 V. N. Iartseva.

Iartseva's interests were on the theory and history of English, general linguistics, and Celtic studies. Her monographs dealing with different aspects of the history of English (morphology, syntax, the formation of literary language) have some specific features concerning the author's methodology, above all her approach to the subjects under investigation. Thus, the morphological structure of Old English is not analyzed from a traditional comparative-etymological point of view but described as a structure of the language of the period. Similarly, the development of a syntactic structure of the language is investigated mostly through structural changes affecting various types of word-combinations, not sentences, because word-combinations are considered to be basic units of language. When analyzing structural changes in English, she took into consideration the interrelationship between categories of different levels and viewed the changes in the context of more general problems. With respect to the development of literary language proper, she paid much attention to the formation of its dialectal basis and to stylistic and genre varieties of the language in their historical succession throughout the territorial and dialectal divisions of England.

The knowledge of many different languages acquired in her postgraduate years accounts for Iartseva's interest in typological problems. She wrote on the definition of a language type, on principles of classification of the world's languages, on methods of comparative and contrastive investigation of languages. In her book *A contrastive grammar* (1981), she came to the conclusion that 'small subsystems' within separate levels of language, especially grammatical subsystems that are formally and semantically correlated, should be taken as the basis for comparative investigation of typologically different languages.

About Celtic studies, she wrote on syntactic and morphological peculiarities that distinguish languages of the group from other Indo-European languages and qualified them as innovations, not as a product of the substratum influence. Her teacher in Celtic studies was Professor A. A. Smirnov, and after his death, she was for some time the only specialist in

this field in her country. At present, many people studying Celtic languages are her pupils.

Iartseva was one of the most active and inspiring personalities among the linguists of her generation in Russia. She was an initiator and chief editor of the multivolume encyclopedia *Languages of the world* (1993–2007), whose books contain descriptions of different groups of languages carried out in accordance with unified typological schemas (14 volumes will be published by 2005, 6 are in preparation). Another project of the kind undertaken on her initiative is the encyclopedia *The languages of Russia and adjacent states* in three volumes (2000–2005). She was also chief editor of *The linguistic encyclopedic dictionary* (1990). Under her supervision, eight conferences were held on problems of Germanic studies, attended by linguists from all regions of the Soviet Union (1956–1988). Iartseva took part in several International Congresses of Linguists as a member of the Executive Committee. In the years of the Cold War, she came into contact with Professor W. P. Lehmann and other American colleagues. Their cooperation brought about a series of conferences on urgent issues of linguistics (typology, semiotics, problems of reconstruction).

Besides research, she was active in lecturing, and at different periods of her life, she was chief of chairs of English philology, Germanic studies, and foreign languages at the universities of Leningrad, Moscow, and Sverdlovsk.

Ibn as-Sarra-j, Muhammad ibn al-Sari- (d. 929)

Z Taha, American University in Cairo, Cairo, Egypt

© 2006 Elsevier Ltd. All rights reserved.

Abou Bakr Muhammad Ibn Sirry is known as Ibn as-Sarraj. The name as-Sarraj is related to the profession of making *suruuj* 'saddles.' He lived in Baghdad and died in 316/929. Ibn as-Sarraj was a student of Mubarrad, Zajjaj, and al-Farabi and started his own class shortly after the death of Mubarrad. He studied logic and music extensively. Several philosophers and logicians admired his style in presenting the information in his books, especially the one entitled *Al-Usul fil nahw*.

Although Ibn as-Sarraj was a Basran, he quoted in his books many of the Kufan ideas, mainly those

this field in her country. At present, many people studying Celtic languages are her pupils.

Iartseva was one of the most active and inspiring personalities among the linguists of her generation in Russia. She was an initiator and chief editor of the multivolume encyclopedia *Languages of the world* (1993–2007), whose books contain descriptions of different groups of languages carried out in accordance with unified typological schemas (14 volumes will be published by 2005, 6 are in preparation). Another project of the kind undertaken on her initiative is the encyclopedia *The languages of Russia and adjacent states* in three volumes (2000–2005). She was also chief editor of *The linguistic encyclopedic dictionary* (1990). Under her supervision, eight conferences were held on problems of Germanic studies, attended by linguists from all regions of the Soviet Union (1956–1988). Iartseva took part in several International Congresses of Linguists as a member of the Executive Committee. In the years of the Cold War, she came into contact with Professor W. P. Lehmann and other American colleagues. Their cooperation brought about a series of conferences on urgent issues of linguistics (typology, semiotics, problems of reconstruction).

Besides research, she was active in lecturing, and at different periods of her life, she was chief of chairs of English philology, Germanic studies, and foreign languages at the universities of Leningrad, Moscow, and Sverdlovsk.

Abou Bakr Muhammad Ibn Sirry is known as Ibn as-Sarraj. The name as-Sarraj is related to the profession of making *suruuj* 'saddles.' He lived in Baghdad and died in 316/929. Ibn as-Sarraj was a student of Mubarrad, Zajjaj, and al-Farabi and started his own class shortly after the death of Mubarrad. He studied logic and music extensively. Several philosophers and logicians admired his style in presenting the information in his books, especially the one entitled *Al-Usul fil nahw*.

Although Ibn as-Sarraj was a Basran, he quoted in his books many of the Kufan ideas, mainly those

of Al-Akhfash Al-Awsat. The following books are attributed to him: *al-uSul*, *mujmal al-uSul*, *al-mujaz*, *al-ishtiqaaq*, *sharh sebawayh*, *ihtijaj al-farraa'*, *al-shìr wal shùara'*, al-riyaah w*al hawa' wal nar*, *al-jumal*, and *al-muwasalat fil axbaar wal mudhakkaraat*.

According to Jamil Allush (1981: 161), the book entitled *al-mujaz* was published in Lebanon in 1965. However, the one book that attracted the attention of very few linguists until now is *al-uSul fil nahw*, which appeared for the first time in 1985.

Ibn as-Sarraj's contributions were especially in the areas of *qiyas, 9illah, and ishtiqaq*. Like all Basran grammarians, Ibn as-Sarraj was notorious for being very strict in *qiyas*. He started a new 'school,' which branched off the main Basran school and called it *madrasat al-qiyas*. After his death, Siyrafi and Ibn Jinni were successively in charge of it. Ibn as-Sarraj criticized Sebawayhi for trying to find a rule to every example that was *masmù* (heard). Ibn as-Sarraj called for discarding such irregularities even though they were "heard, said." For him they were irregularities, and he called the other grammarians to discard them (Dayf, 1983).

There has been a controversy over the content of his book *al-uSul fil naHw*. Later grammarians such as al-Anbari and Ibn Jinni argued that *al-uSul Fil naHw* was only a book on grammar rules. Other grammarians think that *al-uSul* was truly a book on the origins of *naHw*. Some of the supporters were Mohammad Eid, Shawqi Dayf, and Mohammad Amer, in addition to the editors of Ibn Jinni's *Sirr al-Sinàa*.

Perhaps his most pioneering contribution was in the area of syntactico-semantic analysis of the verbal sentence. Ibn as-Sarraj divided verbs into 'real' and 'unreal,' according to the meaning they convey and the morphological features they bear. He approached the concept of transitivity from an original standpoint, where he regarded the direct object of any verb to be an essential part for the meaning of the utterance to be complete. Unfortunately, what he introduced in that respect was not picked up by later grammarians, but rather by linguists such as Al-Jurjani and Ibn Jinni, who looked into the relationship between language and rhetoric.

Ibn Ezra, Abraham (ca. 1089–1164)

A Gianto, Pontifical Biblical Institute, Rome, Italy

© 2006 Elsevier Ltd. All rights reserved.

Abraham Ibn Ezra, grammarian, biblical commentator, poet, philosopher, and astronomer, was born in Tudela in 1089 (some suggest the year 1090 or 1092) and died in 1164 in an unknown locality. He lived in Spain, mostly in Cordoba, until 1140, when he moved, spending long sojourns in Italy (Rome, Lucca, Mantua, Verona), then France (Narbonne, Béziers, Rouen, Dreux) and England (London), and back to Rome via Narbonne.

Enjoying high esteem in Orthodox Judaism as one of the most important authors of biblical commentaries, Ibn Ezra wrote on almost every book in the Hebrew Bible. His interpretations show the influence of Neoplatonism and are often rationalistic. His commentary on the Pentateuch, finished shortly before his death, is one of his most important and authoritative works. His *Yesod Mora* explains the Biblical commandments with some Neoplatonic ideas. He also wrote a number of treatises on mathematics, astronomy, and astrology, such as *Sefer ha-Eḥad,* dealing with the peculiarities of the numbers 1–9, *Sefer ha-Mispar,* or *Yesod Mispar,* on

of Al-Akhfash Al-Awsat. The following books are attributed to him: *al-uSul*, *mujmal al-uSul*, *al-mujaz*, *al-ishtiqaaq*, *sharh sebawayh*, *ihtijaj al-farraa'*, *al-shìr wal shùara'*, al-riyaah w*al hawa' wal nar*, *al-jumal*, and *al-muwasalat fil axbaar wal mudhakkaraat*.

According to Jamil Allush (1981: 161), the book entitled *al-mujaz* was published in Lebanon in 1965. However, the one book that attracted the attention of very few linguists until now is *al-uSul fil nahw*, which appeared for the first time in 1985.

Abraham Ibn Ezra, grammarian, biblical commentator, poet, philosopher, and astronomer, was born in Tudela in 1089 (some suggest the year 1090 or 1092) and died in 1164 in an unknown locality. He lived in Spain, mostly in Cordoba, until 1140, when he moved, spending long sojourns in Italy (Rome, Lucca, Mantua, Verona), then France (Narbonne, Béziers, Rouen, Dreux) and England (London), and back to Rome via Narbonne.

Enjoying high esteem in Orthodox Judaism as one of the most important authors of biblical commentaries, Ibn Ezra wrote on almost every book in the Hebrew Bible. His interpretations show the influence of Neoplatonism and are often rationalistic. His commentary on the Pentateuch, finished shortly before his death, is one of his most important and authoritative works. His *Yesod Mora* explains the Biblical commandments with some Neoplatonic ideas. He also wrote a number of treatises on mathematics, astronomy, and astrology, such as *Sefer ha-Eḥad,* dealing with the peculiarities of the numbers 1–9, *Sefer ha-Mispar,* or *Yesod Mispar,* on

arithmetical questions, and *Luḥot,* which contains astronomical tables. Ibn Ezra's 260 poems are included in his *Diwan*, which also contains the mystical composition *Ḥai ben Mekits* in rhymed prose. In addition to those found in the *Diwan*, he wrote many other poems with religious or secular themes. No work by Ibn Ezra in Arabic has been preserved, although he was known to be perfectly familiar with that language.

Though he did not bring many original insights into the Hebrew language, Ibn Ezra is certainly one of the fathers of Hebrew grammar. His greatest contribution lies in making available the best results of earlier Jewish philologists who wrote in Arabic. It was also Ibn Ezra who introduced European scholars to the triliteral theory of roots, the relation between Hebrew and Arabic, and the basics of poetical meters based on the works of Hayyuj hitherto known only in the more restricted circles of Arabic-speaking scholars.

Ibn Ezra's best-known philological work is *Moznet Leshon ha-kodesh,* also known as *Moznayim*. It contains clear explanations of the grammatical terms used in Hebrew grammar. His best grammatical work is *Sefer Tsaḥut,* which also contains a brief outline of modern Hebrew meter. His *Sefer ha-Yesod*, or *Yesod Dikduk*, is extant only in manuscript. *Safah Berurah* is a treatise on the Hebrew letters. The short monograph on numerals *Yesod Mispar* contains an appendix on the Babylonian-Hebrew system of marking the vowels.

Ibn Janah (ca. 990–1050)

A Gianto, Pontifical Biblical Institute, Rome, Italy

© 2006 Elsevier Ltd. All rights reserved.

The exact dates of Ibn Janah's life are unknown. Presumably he was born at Cordoba sometime between 985 and 990 and died in Saragossa in the first half of the 11th century. He was trained in letters in Lucena, where he also studied medicine and became a skillful physician.

While practicing medicine, he cultivated a great interest in the study of the Bible and the Hebrew language. In 1012, due to some unhappy political circumstance, Ibn Janah and a number of his colleagues had to leave Cordoba. After a considerable period of wandering Ibn Janah settled in Saragossa where he wrote all his works. In that city he also created a center of learning for younger pupils to discuss scientific questions in a free atmosphere. It was for them that he started to write. The traditional circles of Talmudic scholars in Saragossa were sometimes hostile to his approach. Ibn Janah was known to criticize their narrow-mindedness and ignorance, which, as he said, they tried to hide under a mantle of piety. He defended his own efforts by appealing to the example of the Geonim and of the teachers of the Talmud.

The *Kitāb al-Tanqīḥ* (Book of Minute Research) is Ibn Janah's chief work. The work, which is written in Arabic, discusses the Bible and its language, and was the first complete exposition of Hebrew vocabulary and grammar. It does not contain any discussion on vowels and accents which belong to Masoretic works. Yet this work is a rich mine of information on Biblical syntax, rhetoric, hermeneutics, and exegesis. The book has two parts, the first dealing with grammar and the second with lexicography. Each of these parts has a separate name and appears as a separate book. The first part is called *Kitāb al-Luma'* (Book of Many-Colored Flower-Beds). It is preceded by a very interesting grammatical introduction to the entire work and was translated into Hebrew by Judah ibn Tibbon (who translated *Luma'* by *Rikmah*). The second, that is, the lexicographical part of the work, *Kitāb al-Uṣūl*, also has a special introduction. Judah ibn Tibbon also translated it into Hebrew (*Sefer ha-Shorashim*).

For Ibn Janah the study of Hebrew philology was also a religious duty. He is often quoted as saying, "Since the revealed Scriptures can be understood only

arithmetical questions, and *Luḥot,* which contains astronomical tables. Ibn Ezra's 260 poems are included in his *Diwan*, which also contains the mystical composition *Ḥai ben Mekits* in rhymed prose. Ibn Jinni (d. 1200)

S I Sara, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Ibn Jinni was born ʔabu ʔa-fatħ ʕuθmān ʔibn Jinni ʔal-mawsʕilliy (320–392 H/932–1002 A.D.) The two foundational schools of Arabic linguistics were the so-called Basrah and Kuwfah schools, which originated in the 8th century. Their founders, or their most prominent members, were Al-Khalīl (100–175 H/719–791 A.D.) and Sībawayh (140?–180 H/757–796 A.D.) for the Basrah school and ʔal-Kisāʔi. (119–189 H/737–805 A.D.) and ʔal-farrāʔ (144–207 H/761–822 A.D.) for the Kuwfah school. The two schools differed in their approaches to linguistics, and in time the theories of both were spread and practiced at emerging centers of linguistic studies. The Baghdad school of linguistics was one such direct and logical extension, which began more or less on the Kuwfah track of linguistics, with proponents from that school as its leading luminaries, and eventually included representatives of the Basrah school among its ranks. Overall, the members of each school borrowed or followed the arguments of one or the other school as they saw fit, or went their own separate ways and on their own track from the mother schools when they could propose deeper or more compelling arguments for their positions.

Ibn Jinni is at the heart of the Baghdad school of linguistics. He was born in Mawsʕil, in northern Iraq, and got his name 'Jinni' from his Greek father. At age seventeen, he joined the circle of ʔabu ʕaliy ʔal-fārisy (288–377 H/901–987 A.D.), the most prominent linguist of his time, who remained his teacher and mentor for the next 40 years. He traveled with him wherever he went and recorded a great deal of his comments, observations, and sayings, and was also a commentator on some of his writings. He quoted him often under the name of ʔabu ʕaliy, just like Sībawayh quoted Al-Khalīl. The relationship of Ibn Jinni to ʔal-fārisy is parallel to that between Sībawayh and Al-Khalīl. ʔal-fārisy was a fifth-generation linguist after Al-Khalīl, since he was taught by ʔal-mubarrad (210–285 H/825–898 A.D.), who was a fourth-generation linguist after Al-Khalīl of the Basrah school of linguistics. Though he favored the opinions and analyses of the Basrah school of linguistics, referring to the members of the school as *ʔasʕħābunā* 'our associates,' he also sided with some of the opinions and analyses of the linguists of the Kuwfah school, in addition to having his own. This melding was characteristic of the Baghdad school.

Ibn Jinni was a versatile linguist. He was not confined in his interests to linguistic analysis of Arabic, but was a poet in his own right, a man of literature, in addition to his linguistic work in phonetics, morphology, syntax, and semantics in their broad conceptions. He was a friend of the poet Mutanabbi (354 H/965 A.D.) and wrote a commentary on his poetry, as he did on the poetry of another poet, Abu Nuwwās (200 H/815 A.D.). His linguistic orientation veered towards that of the Basrah school, as he referred to the members of the school, in particular Sībawayh and Al-Khalīl, as *ʔasʕħābunā* 'our associates.' He had great interest in words, specifically, lexicon and morphology. To show his great interest in morphology, he wrote a multivolume commentary called *ʔal-munsʕif* on the treatise on *Tasʕriyf* 'derivation' by ʔal-māziniy (249 H/863 A.D.). But Ibn Jinni, despite his deference to his mentor and teacher and the school of linguistics he belonged to, was his own man in linguistics. He was the leading linguist of his generation, and his treatises are monuments to the linguistic literature of Arabic.

The breadth of his linguistic knowledge is reflected in his books. Although it is not possible to touch

by the aid of the science of language, the endeavor to comprehend them from all sides becomes a more imperative duty the higher the end aimed at and the more our reason recognizes the greatness and majesty of Him who has revealed these books."

Ibn Jinni (d. 1200)

S I Sara, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Ibn Jinni was born ʔabu ʔa-fatħ ʕuθmān ʔibn Jinni ʔal-mawsʕilliy (320–392 H/932–1002 A.D.) The two foundational schools of Arabic linguistics were the so-called Basrah and Kuwfah schools, which originated in the 8th century. Their founders, or their most prominent members, were Al-Khalīl (100–175 H/719–791 A.D.) and Sībawayh (140?–180 H/757–796 A.D.) for the Basrah school and ʔal-Kisāʔi. (119–189 H/737–805 A.D.) and ʔal-farrāʔ (144–207 H/761–822 A.D.) for the Kuwfah school. The two schools differed in their approaches to linguistics, and in time the theories of both were spread and practiced at emerging centers of linguistic studies. The Baghdad school of linguistics was one such direct and logical extension, which began more or less on the Kuwfah track of linguistics, with proponents from that school as its leading luminaries, and eventually included representatives of the Basrah school among its ranks. Overall, the members of each school borrowed or followed the arguments of one or the other school as they saw fit, or went their own separate ways and on their own track from the mother schools when they could propose deeper or more compelling arguments for their positions.

Ibn Jinni is at the heart of the Baghdad school of linguistics. He was born in Mawsʕil, in northern Iraq, and got his name 'Jinni' from his Greek father. At age seventeen, he joined the circle of ʔabu ʕaliy ʔal-fārisy (288–377 H/901–987 A.D.), the most prominent linguist of his time, who remained his teacher and mentor for the next 40 years. He traveled with him wherever he went and recorded a great deal of his comments, observations, and sayings, and was also a commentator on some of his writings. He quoted him often under the name of ʔabu ʕaliy, just like Sībawayh quoted Al-Khalīl. The relationship of Ibn Jinni to ʔal-fārisy is parallel to that between Sībawayh and Al-Khalīl. ʔal-fārisy was a fifth-generation linguist after Al-Khalīl, since he was taught by ʔal-mubarrad (210–285 H/825–898 A.D.), who was a fourth-generation linguist after Al-Khalīl of the Basrah school of linguistics. Though he favored the opinions and analyses of the Basrah school of linguistics, referring to the members of the school as *ʔasʕħābunā* 'our associates,' he also sided with some of the opinions and analyses of the linguists of the Kuwfah school, in addition to having his own. This melding was characteristic of the Baghdad school.

Ibn Jinni was a versatile linguist. He was not confined in his interests to linguistic analysis of Arabic, but was a poet in his own right, a man of literature, in addition to his linguistic work in phonetics, morphology, syntax, and semantics in their broad conceptions. He was a friend of the poet Mutanabbi (354 H/965 A.D.) and wrote a commentary on his poetry, as he did on the poetry of another poet, Abu Nuwwās (200 H/815 A.D.). His linguistic orientation veered towards that of the Basrah school, as he referred to the members of the school, in particular Sībawayh and Al-Khalīl, as *ʔasʕħābunā* 'our associates.' He had great interest in words, specifically, lexicon and morphology. To show his great interest in morphology, he wrote a multivolume commentary called *ʔal-munsʕif* on the treatise on *Tasʕriyf* 'derivation' by ʔal-māziniy (249 H/863 A.D.). But Ibn Jinni, despite his deference to his mentor and teacher and the school of linguistics he belonged to, was his own man in linguistics. He was the leading linguist of his generation, and his treatises are monuments to the linguistic literature of Arabic.

The breadth of his linguistic knowledge is reflected in his books. Although it is not possible to touch

upon all of them, a brief glance at the major ones will show the breadth and the depth of his knowledge of Arabic and of the linguistic field in general. In his *Sir sˤināʕat ʔal-ʕi ʕrāb* 'The secret of the formation of ʕi ʕrāb,' he takes up matters that deal with the sound pattern of Arabic. One finds the description of sounds, their classifications, their features, the nature of the segments, weak or strong, the phonetic processes of assimilation, deletion, metathesis, substitution, and the other phonetic processes that make speech a harmonious output.

His book *tasˤriyf ʔal-muluwkiy* 'The royal morphology,' is a treatise that delves in detail into the derivational processes of language, examining both simple and complex morphological forms and the processes that they are subject to. This was, in its way, a follow-up on his commentary on Al-Mazini's treatise. His most ambitious and comprehensive book is *ʔal-Xasˤāʔisˤ*, a work of 162 chapters, which fully displays his linguistic knowledge, his depth of understanding of linguistic issues, the breadth of his vision of Arabic grammar, and the novel manner in which he approached old problems with new and fresh understanding. Here one must mention, by way of example, one of the key issues that he discussed in the book in a new fashion: *ʔal-ʔištiqāq ʔal-ʔakbar* and *ʔal-ʔištiqāq ʔal-ʔasˤɣar* 'the major derivation' and 'the minor derivation.'

ʔal-ʔištiqāq ʔal-ʔasˤɣar 'the minor derivation' involves taking a form, say a tri-radical form like S-L-M, and deriving all the forms from this root without varying the sequential ordering of the three radicals, trying to find the commonality of meanings in all of them. For example, one takes the meaning of *salāmah* 'wholeness/peace' from all its derivations, e.g., *salima* 'he was safe', *yaslamu* 'he is safe', *sālim* 'safe', *salām* 'peace', and so on. The underlying notion is always maintained. *ʔal-ʔištiqāq ʔal-ʔakbar* 'the major derivation' involves taking the six different possible combinations of the three radicals, e.g., of Q-W-L: *q-w-l, q-l-w, w-q-l, w-l-q, l-q-w, l-w-q*, and trying to find a common intent not only in all six but also in all their respective derivations, in the same manner as the common intent was found in one in the minor derivation. This is more complex and demanding; in the case of this root, the commonality is lightness and speed. One can see the challenges that he posed for himself in such tasks. Ibn Jinni is a leading linguistic luminary of the 10th century.

Ibn Madˤāʔ was the Arab Spanish linguist ʔabu ʔal-ʕabbās ʔaħmad ʔibn ʕabd ʔal-raħmān ʔal-laxmiy ʔal-qurtˤ ubiy (513–592 H/1120–1196 A.D.). One must trace the Arabic linguistic movement from its origins to its many destinations if one is to appreciate the issues that different linguists addressed. Its history is quite clear overall: Its origins are clearly the Basrah and Kuwfah schools of the 8th century, where the procedures of data analysis and the nature of valid linguistic data from the Qurʔān, the poets, and dialectal authenticity were set. Although modified over time, these approaches were never abandoned, only enhanced by subsequent generations of linguists. The spread of linguistic doctrines from the Basrah and Kuwfah schools to Baghdad, the center of power and the center of patronage, was natural. In the Baghdad school of linguistics, both schools found adherents, and also were integrated by judicious selection of what was found to be the more compelling in the two schools. Integration and innovation became the hallmark of the Baghdad school. ʔal-fārisy (288–377 H/901–987 A.D.) and Ibn Jinni (320–392 H/932–1002 A.D.), master and disciple, are typical representatives of this school.

upon all of them, a brief glance at the major ones will show the breadth and the depth of his knowledge of Arabic and of the linguistic field in general. In his *Sir sˤināʕat ʔal-ʕi ʕrāb* 'The secret of the formation of ʕi ʕrāb,' he takes up matters that deal with the sound pattern of Arabic. One finds the description of sounds, their classifications, their features, the nature of the segments, weak or strong, the phonetic processes of assimilation, deletion, metathesis, substitution, and the other phonetic processes that make speech a harmonious output.

His book *tasˤriyf ʔal-muluwkiy* 'The royal morphology,' is a treatise that delves in detail into the derivational processes of language, examining both simple and complex morphological forms and the processes that they are subject to. This was, in its way, a follow-up on his commentary on Al-Mazini's treatise. His most ambitious and comprehensive book is *ʔal-Xasˤāʔisˤ*, a work of 162 chapters, which fully displays his linguistic knowledge, his depth of understanding of linguistic issues, the breadth of his vision of Arabic grammar, and the novel manner in which he approached old problems with new and fresh understanding. Here one must mention, by way of example, one of the key issues that he discussed in the book in a new fashion: *ʔal-ʔištiqāq ʔal-ʔakbar* and *ʔal-ʔištiqāq ʔal-ʔasˤyar* 'the major derivation' and 'the minor derivation.'

ʔal-ʔištiqāq ʔal-ʔasˤyar 'the minor derivation' involves taking a form, say a tri-radical form like S-L-M, and deriving all the forms from this root without varying the sequential ordering of the three radicals, trying to find the commonality of meanings in all of them. For example, one takes the meaning of *salāmah* 'wholeness/peace' from all its derivations, e.g., *salima* 'he was safe', *yaslamu* 'he is safe', *sālim* 'safe', *salām* 'peace', and so on. The underlying notion is always maintained. *ʔal-ʔištiqāq ʔal-ʔakbar* 'the major derivation' involves taking the six different possible combinations of the three radicals, e.g., of Q-W-L: *q-w-l, q-l-w, w-q-l, w-l-q, l-q-w, l-w-q*, and trying to find a common intent not only in all six but also in all their respective derivations, in the same manner as the common intent was found in one in the minor derivation. This is more complex and demanding; in the case of this root, the commonality is lightness and speed. One can see the challenges that he posed for himself in such tasks. Ibn Jinni is a leading linguistic luminary of the 10th century.

Ibn Mada'al Qurtubi (1120–1196)

S I Sara, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Ibn Madˤāʔ was the Arab Spanish linguist ʔabu ʔal-ʕabbās ʔaħmad ʔibn ʕabd ʔal-raħmān ʔal-laxmiy ʔal-qurtˤ ubiy (513–592 H/1120–1196 A.D.). One must trace the Arabic linguistic movement from its origins to its many destinations if one is to appreciate the issues that different linguists addressed. Its history is quite clear overall: Its origins are clearly the Basrah and Kuwfah schools of the 8th century, where the procedures of data analysis and the nature of valid linguistic data from the Qurʔān, the poets, and dialectal authenticity were set. Although modified over time, these approaches were never abandoned, only enhanced by subsequent generations of linguists. The spread of linguistic doctrines from the Basrah and Kuwfah schools to Baghdad, the center of power and the center of patronage, was natural. In the Baghdad school of linguistics, both schools found adherents, and also were integrated by judicious selection of what was found to be the more compelling in the two schools. Integration and innovation became the hallmark of the Baghdad school. ʔal-fārisy (288–377 H/901–987 A.D.) and Ibn Jinni (320–392 H/932–1002 A.D.), master and disciple, are typical representatives of this school.

The spread of this linguistic movement followed in the heels of Arab military and political conquest westward, all the way to Spain. In Spain, language analysis in the eastern part of the Abbasid Empire (132–648 H/750–1250 A.D.) was nurtured and vigorously followed. By the 10th century, the Spanish school of Arab linguistics was as dynamic and creative as the schools in the East, especially in Baghdad. Their interests in language mirrored in each other many aspects, although differences existed due not only to the progress in reflection and research on Arabic but also to geography and contacts. Linguists from the East traveled to Spain; and linguists from Spain traveled to the East to study with the masters and then return with their cargo of books and knowledge to the centers in Spain. Linguistic studies, from lexicon to grammar and the other aspects of the language, had reached maturity of development, and serious linguists were beginning to take sides not only on issues, which they had always done in declaring their linguistic allegiance and linguistic preferences, but also on the more critical aspect of analysis and its overall value, say, to the wide use of the *ʕāmil* 'operator' and the teaching of the Arabic language. What one finds in Ibn Madˁāʔ reflects some of the anxiety that comes with the overburdening of the discipline with extra, although necessary, theoretical and other refinements and that seem to go beyond the interest or the comprehension of the ordinary linguist, language teachers, or learners.

Ibn Madˁāʔ favored simplification; one might say he was on the side of the learner, favoring doing away with much of the bewildering theoretical explanations for example, the complexity of reasons for this aspect or that, or the cause of this or that, or the cause of the cause of the same, and so on. He was not only on the side of simplification, but he also had theoretical reservations about what others were saying and doing. He thought he had a solution to the complexity of analysis offered by the ʔal-Naħawiyyuwn 'the grammarians/syntacticians,' and he laid it out in his little treatise called *ʔal-Radd ʕala ʔal-Naħawiyyiyn* 'A refutation of (the) syntacticians,' which attracted and still attracts much attention.

Ibn Madˁāʔ focused on some of the syntactic notions that he wished removed from linguistic discourse. For example, he took issue with linguists from Sībawayh (140?–180 H/757–796 A.D.) to Ibn Jinni on the question of inflectional variation in words as due to a set of *ʕawāmil* 'operators.'

Sībawayh had connected inflectional variation to the presence of the operator; Ibn Jinni elaborated on this, saying that it extended to the speaker doing the act of speech. This led Ibn Madˁāʔ to push it even further and say that God really is the ultimate operator, since the speech of the operator has ceased when one is at the point of articulating the affected item. In sentences like *ʔinna zaidan* (*ʕāqilun*) 'Indeed Zaid is intelligent,' by the time one begins to pronounce 'Zaid,' the operator *ʔinna* has ceased to exist, so it cannot be the cause of the case expression. Since the operator is not always overt/present, Ibn Madˁāʔ concluded that it is not really the cause of variation and one can do away with it. This is the type of argumentation that Ibn Madˁāʔ used to dispose of understood or implied operators in discourse and their implications in being the causes, whether approximate or remote, of the inflectional variations due to syntactic operators.

The approach of Ibn Madˁāʔ was to caricature the positions of other linguists to make them easy targets for his attacks. One would be remiss in not pointing out a similar clash between philosophy and religion at the time. This negative attitude towards operators is all the more curious when one recalls that Ibn Madˁāʔ, the antagonist of causes and operators, was a contemporary of Ibn Rušd (Averroes) (1126–1198), the renowned commentator on Aristotle's philosophical works, the definer and promoter of causes and causality in understanding the reality of things. The attack of Ibn Madˁāʔ parallels the case of ʔabu ħāmid ʔal-ɣazāliy (1058–1111), a Baghdad jurist and theologian, who mounted a similar attack against philosophy and philosophers in his book *Tahāfut ʔal-falāsifah* 'The incoherence of philosophers,' to which the Spanish Ibn Rušd, a jurist and philosopher, responded in his *Tahāfut ʔal-tahāfut* 'The incoherence of incoherence.' This really was an age of high intellectual achievement and the age of challenges and counter-challenges, and Ibn Madˁāʔ, among all the linguists, was very much in the spirit of the age.

Ibn Si-na (980–1037)

S I Sara, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

ʔibn Sīnā (his full name is ʔabuw ʕaliy ʔal-Husain ʔibn ʕabd ʔal-lāh ʔibn Sīnā), is known as Avicenna in the West. He was born in (370H/980 A.D.) in Xarmayθen near Bukhara in modern day Uzbekistan. It is universally acknowledged that ʔibn Sīnā was a man of genius with abundant energy and creativity that he poured into his voluminous contributions to many areas of knowledge. His *kitāb ʔal-šifaʔ* ('The book healing') is the first and the most thorough summa of knowledge ever composed by a single person. It includes all the branches of knowledge, from philosophy and theology to the natural and mathematical sciences. His *ʔal-qānuwn fiy ʔal-tˤib* ('The canon of medicine') is the most renowned medical treatise in the history of medicine. Its 12th-century translation into Latin became the textbook in many European universities in subsequent centuries. There are at least 100 authenticated texts attributed to him and, within a larger sphere of attribution, over 250 items. It is a matter of record that, in addition to his scholarly efforts and output, he was involved in politics, which might partially explain his frequent moves and changes of patronage and political allegiances, as we are reminded in his autobiography (Gohlman, 1974). The miracle of ʔibn Sīnā is that despite all his restlessness; his move from place to place; his changes of patronage; and his sybaritic, bachelor style of life, he managed to write and accomplish so much original work in many fields of knowledge, as indicated in Afnan (1958).

Among all of this superabundance, his linguistic contribution is seldom pointed out. There is a reference in his autobiography to an embarrassing episode where his linguistic competence in Arabic was challenged in the presence of his patron. As a result, he dedicated three years to the study of the language and wrote then a book *lisān ʔal-ʕarab* ('The Language of the Arabs'). (Gohlman, 68–70). The work has been lost. The only linguistic treatise that has come down to us is his *Risātat ʔasbāb ħuduwf ʔal-ħuruwf* ('Treatise on the causes of the occurrence of letters'), written at the request of his patron, ʔemir ʔabuw mansˤuwr ʔal-ʤabbān. Both the conception and execution of this treatise are remarkable. We have no evidence that there was any scientific and objective research on phonetics at the time of ʔibn Sīnā, but he wrote a fully articulated treatise, in six chapters, that includes all aspects of phonetics, as the titles of its chapters indicate: 1. On the cause (*sabab*) of the occurrence (*ħuduwf*) of sound (*is awt*); 2. On the cause (*sabab*) of the occurrence (*ħuduwf*) of letters (*ħuruwf*); 3. On dissection (*tašriyħ*) of the (*ħanʤarah*) larynx and the tongue (*lisān*); 4. On the detailed causes (*asbāb*) for each (*ħarf*) letter of the letters (*ħuruwf*) of the Arabs; 5. On the letters (*ħuruwf*) that are similar (*sabiyha*) to these letters (*ħuruwf*), but are not in the language (*luɣah*) of the Arabs; 6. On the fact that these letters (*ħuruwf*) may be heard in other than articulatory motions (*ħarakāt nutˤ qiyyah*).

This is the first treatise that speaks of phonetics in such an original and holistic manner until our times, almost 10 centuries later. Reflecting on the manner and matter of this treatise, one regrets all the more the loss of *lisān ʔal-ʕarab* ('The language of the Arabs') and its treasure of linguistic insights into Arabic by this man of genius. ʔibn Sīnā died in Hamadān in 1037.

Iceland: Language Situation

M K C MacMahon, University of Glasgow, Glasgow, UK

© 2006 Elsevier Ltd. All rights reserved.

Icelandic, the national language of the Republic of Iceland, is spoken by a population of about 280 000. It is the language of government, politics, civil administration, religion, education, the press, and the media. Specialist scientific periodicals tend to use English as their official language. In schools and in institutions of higher education, Icelandic is the official language of instruction. The level of literacy throughout the country is extremely high (almost 100%).

Since 1999 the first foreign language to be taught in Icelandic schools is English. Before that it was Danish.

Among domiciled immigrants to Iceland, who make up a very small proportion of the population, the foreign languages that are most in use are English, Danish, Swedish, and Norwegian (Norwegian Nynorsk). As a result of emigration from southeast Asia in the late 1970s, there is a small group of Vietnamese speakers in Iceland.

Icelandic is spoken natively outside Iceland only by expatriates, who currently number about 17 000 and use it for social purposes only. The majority of such speakers live in Canada and the United States, but there are a few hundred each in most West European countries.

Iconicity

J Haiman, Macalester College, St. Paul, MN, USA

© 2006 Elsevier Ltd. All rights reserved.

Iconicity is the idea that a formal property in a sign corresponds through similarity to a property of its referent. The idea was entertained and then rejected by Plato in the *Cratylus*. Plato's conclusion was restated by Saussure as "*l'arbitraire du signe*" and has been a mainstay of all versions of structuralism, including notably generative grammar (cf. Hockett, 1960; Chomsky, 1969). Most standard textbooks dismiss the topic with examples of individual words: *whale* is a small word for a large animal; *microorganism* is a large word for a small one; QED. The relationship between form and meaning is considerably more interesting than this once we analyze complex signs and sign systems using the notion of diagrammatic iconicity introduced by Peirce (1932), or indeed, Saussure's closely related notion of motivation. A diagram is an attenuated icon if the relationship among its parts in some way approximates the relationship among the elements to which these parts refer. Standard examples of the apparent diagrammatic iconicity of language then include the universal principle of isomorphism, which as a cognitive principle is largely responsible for the operation of grammatical analogy (i.e., "One form should correspond to one concept"). This can be thought of as the iconicity of paradigms. Other standard examples that correspond more to Saussure's motivation include the semantic compositionality of *dix-neuf* and other compounds; Behaghel's first law ("physical closeness corresponds to conceptual closeness";

Iceland: Language Situation

M K C MacMahon, University of Glasgow, Glasgow, UK

© 2006 Elsevier Ltd. All rights reserved.

Icelandic, the national language of the Republic of Iceland, is spoken by a population of about 280 000. It is the language of government, politics, civil administration, religion, education, the press, and the media. Specialist scientific periodicals tend to use English as their official language. In schools and in institutions of higher education, Icelandic is the official language of instruction. The level of literacy throughout the country is extremely high (almost 100%).

Since 1999 the first foreign language to be taught in Icelandic schools is English. Before that it was Danish.

Among domiciled immigrants to Iceland, who make up a very small proportion of the population, the foreign languages that are most in use are English, Danish, Swedish, and Norwegian (Norwegian Nynorsk). As a result of emigration from southeast Asia in the late 1970s, there is a small group of Vietnamese speakers in Iceland.

Icelandic is spoken natively outside Iceland only by expatriates, who currently number about 17 000 and use it for social purposes only. The majority of such speakers live in Canada and the United States, but there are a few hundred each in most West European countries.

Iconicity

J Haiman, Macalester College, St. Paul, MN, USA

© 2006 Elsevier Ltd. All rights reserved.

Iconicity is the idea that a formal property in a sign corresponds through similarity to a property of its referent. The idea was entertained and then rejected by Plato in the *Cratylus*. Plato's conclusion was restated by Saussure as "*l'arbitraire du signe*" and has been a mainstay of all versions of structuralism, including notably generative grammar (cf. Hockett, 1960; Chomsky, 1969). Most standard textbooks dismiss the topic with examples of individual words: *whale* is a small word for a large animal; *microorganism* is a large word for a small one; QED. The relationship between form and meaning is considerably more interesting than this once we analyze complex signs and sign systems using the notion of diagrammatic iconicity introduced by Peirce (1932), or indeed, Saussure's closely related notion of motivation. A diagram is an attenuated icon if the relationship among its parts in some way approximates the relationship among the elements to which these parts refer. Standard examples of the apparent diagrammatic iconicity of language then include the universal principle of isomorphism, which as a cognitive principle is largely responsible for the operation of grammatical analogy (i.e., "One form should correspond to one concept"). This can be thought of as the iconicity of paradigms. Other standard examples that correspond more to Saussure's motivation include the semantic compositionality of *dix-neuf* and other compounds; Behaghel's first law ("physical closeness corresponds to conceptual closeness";

cf. Bolinger, 1975; Bybee, 1985; Haiman, 1985); several apparently universal ordering principles, such as the order of clauses in a narrative (*I came, I saw, I conquered*; cf. Jakobson, 1965) or in conditional constructions (protasis precedes apodosis; cf. Greenberg, 1966) corresponds to the conceptual or real-time order of the states to which the propositions refer; and the various uses of repetition and reduplication (cf. Moravcsik, 1978), such as XX typically means plurality, distributivity, iterativity, or emphasis of whatever is denoted by X. This type of motivation can be thought of as the iconicity of syntagms.

It is now widely recognized that systematic correspondences do exist between linguistic diagrams and extralinguistic reality, but the nature of these correspondences is often debated. Following Zipf (1935), it is now acknowledged that a principle of least effort is involved in the creation of linguistic structures, such that familiar, frequently mentioned and unsurprising concepts tend to be given reduced expression. We talk about cars and TV rather than automobiles and television, and there is no language known in which the words for *man* and *woman*—for all the inexhaustible fascination, mystery, and complexity of their referents—are seven-dollar words. It even seems that we consciously control the contrast between fuller and more reduced expressions of the same phonetic strings, depending on whether they are formulaic or novel (Van Lancker and Canter, 1981; Van Lancker, Canter, and Terbeek, 1981), or on whether they are to be interpreted as common nouns or anaphors (Haiman, 2003).

In some cases, the relationship between the reduction (and opacity) of a form and its predictability can be scalar, with different points along a linguistic continuum corresponding with different points along a conceptual continuum, exactly in accordance with an elaboration of Zipf's principle. A striking example is a correlation discovered and defined by Givon (1985) that seems to have considerable cross-linguistic validity: the length and complexity of an anaphoric expression will tend to covary with the remoteness in discourse of its antecedent, all the way from a full noun phrase down to zero. Givon considered this to be an iconic covariation, although the Zipfian motivation for the pattern is apparent.

Challenges to the principle of iconicity today take two forms. The first approach consists in demonstrating that many examples of iconicity in the literature (including possibly all variations on the markedness principle that "more form corresponds to more meaning") can be reduced, like Givon's principle, to economically motivated reductions, the basic principle being to give lesser expression to what is familiar or predictable. For example, the third-person singular of verbal and nominal paradigms is frequently zero. It could be that this is an icon of the third person as "the absent one" (cf. Benveniste, 1946), but it could be an economically motivated reduction of the most frequently occurring case. Iconicity would then be purely incidental, an epiphenomenal consequence of another drive.

The second approach consists of acknowledging the possible importance of iconicity in primitive signaling between speakers who share no common conventions—perhaps speakers of different languages, perhaps primitive speakers of the first human languages (cf. Grice, 1989: 358, whose insistence that "every artificial or non-iconic system is founded upon an antecedent iconic system" is an expression of this view)—but then emphasizing that through conventionalization iconicity will be very rapidly lost. First come charades and onomatopoeia (indeed, common sense makes us ask what other means there might possibly be at speakers' disposal), but, once speakers share a common culture, all the conventional features of normal grammar will rapidly appear in their communication, sometimes within a matter of minutes (cf. Bloom, 1979). Although it may seem like no more than common sense that speakers will find it easier to store and process icons than symbols (Givon, 1985), there is little solid evidence that has been adduced in support of this contention. In fact, Benveniste (in linguistics) and Berger and Luckmann (in culture) have recognized that people tend to accept whatever they are familiar with as perfectly natural and to reject all alternatives as alien and barbaric (cf. Anderson, 1990). Motivation, in this view, derives entirely from conventions that are "always already there." In a way, the argument from convention is related to the argument from least effort because much of the opacity of conventions results from streamlining. But this argument is one that should make the analyst even more skeptical about the possibility of encountering iconicity in any recorded language. If iconicity can be lost within 15 or 20 minutes in a contrived encounter, then what are the chances we will encounter it in languages that have been spoken for any longer than this time? To survive at all, it must be constantly recreated.

To counter such reasonable skepticism, it is necessary to demonstrate that iconicity is an independent and currently productive drive in the genesis of linguistic structures. The constant operation of analogy and the rarity of perfect synonymy may be taken as

evidence for the psychological reality of isomorphism or the iconicity of paradigms ("one form corresponds to one meaning"). The iconicity of syntagms is a different matter.

The best evidence for the psychological reality of motivation is the fact that where there are competing structures with roughly the same meaning, speakers will tend to select the form that corresponds to the specific meaning they prefer on the basis of motivation. Stock examples are the contrasts between *hair* (mass noun) and *hair-s* (count noun) or between *kill* and *cause to die* (cf. Wierzbicka, 1980, 1985). But it could be argued that the choice between preexisting structures is not the same as the creation of novel ones and thus provides at best pale evidence for the reality of motivation.

It may seem that the tension between iconic and economic or Zipfian motivation may be a straightforward one that reflects the competition noted by Passy (1890) and von der Gabelentz (1891) between the drive for clarity, on the one hand, and the drive for ease, on the other. Cases such as Givon's topic accessibility hierarchy and the motivation for the reduced expression of anaphors in general indicate that often the same formal contrasts may have one interpretation here and another one there.

Another example explicitly dealt with by Haiman (1985) is the contrast between light and heavy versions of the reflexive in a number of unrelated languages, including English. Given that there exists a conceptual contrast between introverted actions that people typically perform on themselves (verbs of grooming, dressing, and change of posture) and extraverted actions that they more typically do unto others, the Zipfian principle of economic motivation predicts that the light form of the reflexive is used where the verb is introverted, whereas the heavy form is used where the verb is extraverted. This is borne out in English and in almost all the languages where the light/heavy distinction for reflexives exists:

I shaved.
I kicked myself.

But there is another conceptual contrast that the same morphological distinction expresses. Light reflexives are typically middles or impersonal passives, that is, one-participant activities (cf. Langacker and Munro, 1975; Haiman, 1976). Heavy reflexives never function as impersonal passives because the heavy reflexive morpheme (typically a separate nominal expression) marks a second participant. Thus, the contrast between the next two sentences.

I got up.
I got myself up.

The strong sense of reflexives such as *I got myself up* in English is of a divided or alienated self. In this particular sentence, the subject denotes the will, the object the flesh. In languages that form their impersonal passives via a reflexive construction, such as Russian, the contrast is:

videt-sja
see-3.SING.REFL
's/he is seen, is visible'

videt sebja
see-3.SING self
's/he sees him/herself' (as in a mirror)

The sense of a divided self is, admittedly, weak in textbook cases of reflexivization involving mirrors (person vs. image of person), but recurs with overwhelming frequency in natural discourse, which is filled with descriptions of people who force themselves to do things they do not want to do, pat themselves on the back, feel proud of or sorry for themselves, hate themselves for their weakness, and so forth (cf. Haiman, 1998: Chap. 5, and the references cited there). Exactly the same formal contrast (light/heavy reflexives) can be iconically or economically motivated.

The light reflexive participates in another contrast, between intransitive and transitive verbs that involve a change of state. In those cases in which the verb root for related transitives and intransitives is the same, there are a number of possible means of expressing the contrast via derivational affixation (see Table 1). Sometimes one language will make the intransitive the basic form, while another language makes the transitive the basic form for the same verb. Thus in English, the verb *bear* (a child) is basically transitive, and the intransitive is the derived passive *be born*. In Turkish, the verb 'be born' is basic *dog-*, and the verb 'bear' is the derived causative *dog-dur-*. But the contrast is not an entirely random one. Zipfian considerations of economy lead us to expect that typically verbs that are generally performed on others will have the bare stem in the transitive and a derived mediopassive in the intransitive, whereas verbs that

Table 1 Affixation and transitivity

Intransitive	*Transitive*
Bare stem	Bare stem + causative
Bare stem + reflexive passive	Bare stem

are conceived of as spontaneous actions will more typically occur in the unmarked form in the intransitive, with a derived causative for the transitive. This is what Haspelmath (1993) found to be the case in a survey of 31 verbs in 21 languages – some complex derived expression (the anticausative) is favored for the intransitives formed from verbs such as *break*, where it is more probable that an outside force brings about the event. Conversely, actions such as *freeze,* which typically occur without an outside instigator, can be made transitive by the addition of some causative. So, the contrast is exactly parallel to that between introverted and extroverted reflexives, and is a function of purely economic principles: reduced expression is given to the predictable.

The presence of Iconicity can most clearly be demonstrated when it comes into conflict with economy and trumps it. Such cases are well known and leave no room for ambiguity. The most striking examples come from the expression of symmetry. Haiman (1985) showed that in Hua (Yagaria), the expression of reciprocity, a symmetrical relationship, cannot be given by a reciprocal pronoun (there are none) nor by straightforward sentential coordination because the structure S1 + S2, as in many Papuan languages, exhibits a morphological asymmetry between the first (medial) and the second (final) clause. The medial verb occurs with two verbal desinences M (medial) and A (anticipatory), which agree with the subject of S1 and S2, respectively, whereas the final verb occurs with a totally distinct F (final) desinence, which agrees with the subject of S2 alone. The morphological asymmetry of the verbal desinences (verb of S1 = V + M + A; verb of S2 = V + F) reinforces the syntactic asymmetry of order, so that a coordinate sentence such as S1 ['Max hit Harry'] S2 ['Harry hit Max'] can mean only something like 'Max hit Harry and thereupon/therefore Harry hit Max'. The problem of reciprocal symmetry is solved in Hua by making the second verb also into a medial verb whose M desinence agrees with the subject of S2 and whose A desinence agrees with the subject of S1. The whole coordinate construction, which models a closed ring, is treated as a nominalization that occurs with a light final verb that agrees with the subject of S1 + the subject of S2.

ebgi-ga-na	ebgi-ga-na ha'e
hit-3.SING.M-3.SING.A	hit-3.SING.M-3.SING.A do.3DL.F
'they hit each other'	

where DU indicates Dual. There is a more economically motivated way of saying this, which consists of stripping both the medial verbs of their personal desinences and nominalizing the verb stems by affixing the glottal stop:

ebgi-'	ebgi-' ha'e
hit-NOM.	hit-NOM. do.3.DL
'they hit each other'	

The latter does justice to both iconicity and economy, but the first satisfies iconic imperatives alone.

In the same way that we need to distinguish iconic from economic motivation, we have to separate iconically motivated symmetry of this sort from other cases that seem to be motivated by yet other drives. The drive for symmetry without iconic motivation is abundantly attested in a number of Southeast Asian and Oceanic languages. There is an enormous literature on this topic, some of which is summarized in Fox (1988). A particularly striking (if modest) example from English, first noted by Alan Cruttenden, is the phenomenon of radio announcements of tied scores, for example, *Sussex 2, Essex 2*. From the point of view of information structure, both scores are new information and should be read with the same intonation as *Sussex 2, Essex 3*. Yet they are not, with the paradoxical result that listeners hearing only *Sussex 2*... can turn off the radio because they already know the score. It is probable that announcers seeing the symmetrical segmental structure XY ZY before them assign it a (cognitively inappropriate but esthetically motivated) noniconic symmetrical intonation XyZy.

Because the results of an iconic imperative are constantly being eroded by other drives, and compromised in any event by the natural limitations of the one-dimensional auditory medium of language, cases in which it is nevertheless apparent are heuristically useful. A routinely exploited heuristic consequence of the principle of isomorphism is that recurrent cross-linguistic identity of form between two or more grammatical constructions must be a reflection of a perhaps unsuspected semantic commonalty; for example, such a commonalty is exhibited by protasis clauses in conditional sentences and sentential topics, whose semantic identity is now widely recognized (cf. Podlesskaya, 1992). A parallel heuristic consequence of the principle of motivation is that when a given construction recurrently exhibits formal symmetry, this formal symmetry is a reflection of possibly unsuspected conceptual symmetry; such a pattern is exhibited by the protasis and apodosis clauses of counterfactual conditional sentences, and a plausible semantic account for this symmetry has been offered by Haiman and Kuteva (2003).

Given that iconicity is widespread in human languages and given that the forces of conventionalization

immediately attack and destroy iconicity, the central problem is accounting for the fact that it nevertheless endures. For this to be so, it is not enough to suggest that iconicity was the original state of some conjectured proto-language. Rather, iconicity must be constantly created. Although it has been optimistically proposed that there are cognitive motives for iconicity, no evidence has ever been presented that iconic forms are easier to store or to access than symbolic ones. This suggests that an essentially esthetic impulse (perhaps simply the impulse to reproduce a given structure) is responsible for the creation of iconic forms (cf. Haiman, to appear).

Iconicity, Sign Language

S Wilcox, University of New Mexico, Albuquerque, NM, USA

© 2006 Elsevier Ltd. All rights reserved.

'Iconicity' is a term coined by C. W. Morris (1901–1979; *see* **Morris, Charles (1901–1979)**) that designates the measure of similarity between a sign and the object to which it refers (Bussmann, 1996: 215). The nature of this relation has been discussed and debated since antiquity. Jakobson (1990) traces the crucial question of iconicity's role in language, whether language attaches form to content by nature (*physei*) or by convention (*thesei*), to Plato's dialogue *Cratylus*. Socrates, the moderator of this debate, tends to think that representation by similarity is superior to the use of arbitrary signs but in the end tends to accept the position that conventionality plays a major role in language.

In American linguistics, Dwight Whitney (1827–1894; *see* **Whitney, William Dwight (1827–1894)**) also came down on the side of convention and was instrumental in a worldwide acceptance of the definition of language as a system of arbitrary and conventional signs. Perhaps the most influential linguist on this topic was Ferdinand de Saussure (1857–1913; *see* **Saussure, Ferdinand (-Mongin) de (1857–1913)**), who, following Whitney, maintained that "the bond uniting the signans with the signatum is arbitrary" (Saussure, 1916: 67).

Linguists in the functionalist and cognitive schools often regard iconicity as an essential feature of language (Haiman, 1985). Givón's iconic imperative states that "all other things being equal, a coded

experience is easier to store, retrieve and communicate if the code is maximally isomorphic to the experience" (Givón, 1989: 97). Croft regards iconicity as a major type of external motivation for linguistic structure. In his view, the operating principle of iconicity is that "the structure of language reflects in some way the structure of experience, that is to say, the structure of the world, including (in most functionalists' view) the perspective imposed on the world by the speaker" (Croft, 1990: 164). Croft's view, which emphasizes the speaker's cognitive construal of the world, is compatible with modern cognitive linguistic theories, in which iconicity plays a major role.

Iconicity in Signed Languages

Signed languages, because of their visual modality, are particularly rich in iconicity. Much of the early work on American Sign Language (ASL), while it recognized the pervasive presence of iconicity, devoted its attention more to reducing the significance of iconicity than to studying what it tells us about grammatical structure. For example, studies examined the loss of iconicity over time in the lexicon (Frishberg, 1975), demonstrated that iconicity does not appear to play a role in language acquisition (Meier, 1980), and concluded that iconicity does not aid in the processing of signs (Klima and Bellugi, 1979).

Recent research has called into question some of these claims about the role of iconicity in signed languages. For example, Grote and Linz (2003) addressed whether the form of signs influences a signer's representation of the semantic domain of a sign's referent, particularly in the case of iconic signs. They hypothesize that the iconic relationship between a sign and its referent is not created purely via a likeness but is the result of "a mentally constructed correspondence between two cognitive products" (25). In one experiment investigating iconicity, deaf signers of German Sign Language, hearing speakers of spoken Standard German, and hearing bilinguals (Standard German/German Sign Language) were presented with a German Sign Language sign or a Standard German word, followed by a picture, and were asked to decide whether there was a semantic relationship between the two. Some of the pictures represented the iconic base of a German Sign Language sign, such as the beak of an eagle. Other pictures represented semantic features unrelated to the iconic base of a sign, such as the claws or the wings of an eagle. Finally, some pictures were completely unrelated to the sign or word they were paired with. Grote and Linz found that the deaf and hearing signers were faster to respond to pictures of the iconic base of a sign than to pictures that depicted other semantic features of the sign's meaning. Interestingly, the same pattern of results was found when the bilinguals were tested in Standard German.

Despite studies of this nature, the role of iconicity in signed language grammar is still quite controversial. An indication of how far the rejection of iconicity in grammar has gone is exemplified in Valli and Lucas (1995: 7), who note that while iconicity is present in the lexicon, iconicity "will not provide much insight into the interesting relationship between SIT and the noun CHAIR, and other noun-verb pairs. Nor will [iconicity] help explain how the movement of SIT can be modified to mean SIT FOR A LONG TIME (slow, circular movement) or SIT ABRUPTLY (short, sharp movement)."

Wilcox (2004) argues that the grammatical categories of noun and verb in ASL noun-verb pairs do exhibit an iconic relation. Nouns profile a bounded region in space both semantically and phonologically. Verbs profile phonological movement in space; semantically, movement in space is a prototypical example of a process, a defining property of the category 'verb' (Langacker, 1987). The descriptions of the two aspectual verb forms are striking in how transparently they demonstrate the iconic relation between meaning and form: slow, circular movements indicating the durative form and short, sharp movements indicating the punctual form.

Even those linguists who did acknowledge iconicity generally accepted that it played little role in the grammar of ASL. Klima and Bellugi (1979), for example, while recognizing the "two faces of signs: the iconic face and the encoded, arbitrary face" (70), concluded as follows:

> The iconic face does not show at all in the processing of signs in immediate memory. Historical change diminishes the iconic properties of ASL signs; some signs become more opaque over time, some completely arbitrary. (79)

Further, Klima and Bellugi claimed that the grammar of ASL works to override or submerge the inherent iconicity of signs:

> Grammatical operations that signs undergo can further submerge iconicity. Thus many signs, while having their roots deeply embedded in mimetic representation, have lost their original transparency as they have been constrained more tightly by the linguistic system. (34)

Using a cognitive iconicity analysis, Wilcox (2004) came to a different conclusion, arguing that although iconicity erodes in the lexicon, it emerges in the grammar. Cognitive iconicity is based on the theoretical model of cognitive grammar (Langacker, 1987), which claims that both semantic and phonological structures reside within a language user's conceptual

space. The typical case for language is that the semantic and the phonological poles of symbolic structures reside in distant regions of conceptual space. This great distance in conceptual space is the basis for Saussure's contention of "*l'arbitraire du signe*." Alternatively, when the phonological and semantic poles of signs reside in the same region of conceptual space, arbitrariness is reduced. According to the cognitive iconicity model, iconicity is regarded as a distance relation between structures that reside in multidimensional conceptual space (Gärdenfors, 2000). Cognitive iconicity thus is defined, not as a relation between the form of a sign and the real-world referent, but as a distance relation within our multidimensional conceptual space between the phonological and semantic poles of symbolic structures.

Cuxac (1999) adds the important notion of iconic intent. According to his model, iconicity is split into two subbranches according to whether or not it serves to represent experience iconically. The standard lexicon is composed of signs "without iconic intent." Cuxac calls signs formed with iconic intent "highly iconic structures" and regards these to be a highly distinctive feature of signed languages. Several types of highly iconic structures are identified, including transfers of size and form, transfers of situation, and transfers of person.

Several researchers have explored the link between iconicity and metaphor. According to Taub (2001), what is unique about signed languages is the way that iconicity and metaphor combine to create a "double mapping." In spoken languages, a metaphorical expression maps language about a concrete domain onto an abstract domain. In a signed language, the iconicity of the source-domain signs can be directly manipulated such that metaphorical expressions are a combination of (1) an iconic mapping between the source domain and the articulators and (2) a metaphorical mapping between the source domain and the target domain.

Also examining the relation between metaphor and iconicity, Bouvet (1996) investigated the semiotic basis of iconic signs in French Sign Language and argued that in many cases, the relationship between a sign and its referent is grounded in metaphorical projections of embodied, iconic representations. Bouvet demonstrated how signs for abstract concepts reveal a metaphorical projection of the conceptual domain onto the domain of the human body.

Iconicity in signed languages is receiving more research attention than ever before. In addition to studying iconicity as an instance of conceptual mapping, researchers have begun to examine its relationship to other cognitive processes, such as metaphor and metonymy (Brennan, 1990; Taub, 2001; P. Wilcox, 2000; Wilcox, Wilcox, and Jarque, 2004) as well as variation in iconicity by discourse context (Russo, 2004).

It appears that our understanding of the relation between *signans* and *signatum* greatly depends on the data that are studied. Historically, linguists based their understanding of the extent and theoretical significance of iconicity on data derived entirely from spoken languages, which led to the conclusion that iconicity was not an essential feature of the language system. Functional studies changed that view, leading Haiman (1980) to conclude that the structure of thought reflects the structure of reality to an extent greater than previously thought.

When data from signed languages are considered, iconicity becomes a far more common phenomenon with broad implications for our understanding of language and cognition. Wilcox (2004), for example, suggests that iconicity is symptomatic of an underlying unity of phonological and semantic space as domains within our conceptual space and that iconic congruence across these domains emanates from a common conceptual system that underlies and structures linguistic form and meaning.

Iconicity: Theory

Iconicity Precedes Conceptual Signs

Starkly put, iconicity comes about through some resemblance between something and something else, and a sign is iconic if there is some resemblance between that which represents and that which is represented. But problems immediately arise, and they can be properly addressed only with some qualification of a sign as iconic.

Charles Sanders Peirce's semiotic theory in its most basic form specifies three different sign types – icons, indices, and symbols – and these are correlated with his three categories of the world's processes and of mental processes, Firstness, Secondness, and Thirdness. These three categories are briefly defined as follows:

1. Firstness *is* what *is*, and has not (yet) entered into any interrelation with any *other*. In this sense, it is no more than possibility. An icon, in and of itself, is a sign of Firstness: it is what it is, insofar as some resemblance between it and something else has not (yet) been foregrounded. (Examples: a triangle as an icon of some mountain, or a cloud formation as an icon of waves breaking when they head toward a beach.) Notice that there is neither foreground nor background: there is no more and no less than that which is.
2. Secondness *is* what *is*, insofar as it bears some interrelation with some *other* that it *is not*, though that interrelation has not (yet) been foregrounded by some potential interpreting agent. Secondness is actuality or existence, whether in the mind or in the physical world. An index as a sign chiefly of Secondness is something interrelated with something else by a physical or presumably 'real' interaction with that something else. (Examples: smoke and fire, a cup and its content, an arrow and what it indicates, or a thermometer and air temperature.) Notice that the interrelation involves interaction that is a matter of causality, contiguity, container–contained, or part–whole. Notice also that the index is a sign of some *particular* existent mental or physical world entity, and does not (yet) evince the idea of a general class of entities of which the sign could potentially be a sign.
3. Thirdness *is* what *is*, insofar as it brings about (mediates) an interrelated interaction between something and something else in the same way that it enters into the same interrelated interaction with that something and that something else. Thirdness entails mediation of something and something else by a third entity, leading to some motivated or otherwise potential or necessary interpretation. A symbolic sign is something that

Iconicity: Literary Texts

Introduction

Definition

In a general sense, semiotic iconicity may be defined as form miming form as when pictures or photographs reflect an object in the real world. In a language context, a 'sign' (which may be a word or an assemblage of words) is said to mime the object or thought that the sign refers to when something in the sign (be it oral/aural or visual) reflects something in the object that is signified by it (its 'referent'). More generally, it can then be said that the sign mimes its meaning. The term 'iconicity' goes back to Morris who introduced it in his *Signs, language, and behavior* in 1946. Traditionally, the iconic sign has been divided into three hypo-icons, namely **image**, **diagram** and **metaphor**. Although all three hypo-icons play a significant role in natural as well as literary language, metaphor has been much more extensively discussed and mainly outside the context of iconicity (*see* **Metaphor: Stylistic Approaches**). Metaphor is also different from the other two hypo-icons in that there is no 'direct' iconic relation between the sign and its referent. Instead, it is based on a proportional analogy, whereby an existing sign x is extended to include a new, metaphorical referent because of a semantic analogy between the original referent α and the new one β. In other words, there is no direct relation between the level of form and referent, neither an 'imagic' one nor a 'diagrammatic' one. The differences can be represented as follows, in which $\updownarrow$ indicates an iconic relation, and $\neq$ a symbolic one:

image	*diagram*	*metaphor*		
sign	mapping of signs	sign x	$\rightarrow$	sign x
$\updownarrow$	$\updownarrow$	$\neq$		$\neq$
referent	mapping of referents	referent α	$\leftrightarrow$	referent β

This definition of iconicity is a strictly semiotic one. Nöth (2001) further differentiates between **exophoric** and **endophoric iconicity** (sometimes also called first- and second-degree iconicity). Whereas exophoric iconicity consists primarily in form miming an object or thought as we perceive it in the world, endophoric iconicity refers to a sign miming another sign (thus being purely intralinguistic); involving, in other words, the repetition of a sign. Even though endophoric iconicity is concerned with resemblances between signs, and not between the sign and the referent, such a repetition is only considered of literary interest when used with effect, i.e., when it adds extra meaning to the text.

Next to the **icon**, there are two other types of signs, the **index** and the **symbol**. The index is, like the icon, motivated, but not by resemblance to its referent but by relations of contiguity or causation. The symbol is a conventional sign, and its relation to the referent is arbitrary. It has to be noted that these three categories are not sharply delineated, symbols often develop out of motivated signs, and many icons also have an indexical relation with their referent (cf. White, 1999).

Image versus Diagram

'Images' or 'imagic icons,' that is, signs whose form is related to the referent by means of a 'natural' similarity, are often said to be exceptional in (spoken) language and restricted to a category of acoustically imitative words labeled 'onomatopoeic,' e.g., 'meow,' 'cuckoo.' (In visual language, i.e., in written and especially in signed language, the 'image' plays a larger role.) For this reason, structuralist and formalist linguists since de Saussure have underestimated the importance of iconicity in language. However, as most notably R. Jakobson (1971) kept pointing out, things begin to look different when C. S. Peirce's crucial distinction between the 'image' and the 'diagram' is adopted. In Peirce's taxonomy of signs, an iconic image is a single sign that resembles its referent with respect to some visual or aural characteristic. An iconic diagram, however, is an arrangement of signs, none of which necessarily resembles its referent but whose relationships to each other mirror the relationships of their referents. Thus, in Caesar's famous phrase '*veni, vidi, vici*,' the sequence of individually symbolic words presents an iconic diagram of the sequence of actions it enumerates.

Although conceding the arbitrary or 'symbolic' nature of the individual linguistic sign in isolation, a number of linguists in Jakobson's wake have emphatically drawn attention to the near universality of diagrammatic iconicity in the grammars of various languages, expressing not only chronological sequence, but also centrality versus peripherality, distance versus proximity, symmetry, quantification, etc. It is in the nature of literature to exploit all linguistic forms and, hence, also all iconic possibilities for aesthetic purposes.

History of Iconic Criticism of Literature

Whereas the study of iconicity in everyday language has become an accepted part of modern linguistics,

this is less the case with the literary uses of it. Because of an uninformed reduction of the notion of iconicity to that of imagic signs only, a restricted field of investigation offered itself to literary criticism along iconic lines. Thus, traditionally, the main objects of iconic investigations by literary scholars have been the literary use of onomatopoeia and sound symbolism, on the one hand, and of typography in pattern poetry and modern visual poetry, on the other. The presence of iconic diagrams in literary texts has been largely ignored. These mainly occur on the level of morphosyntax and discourse, although they also may be present on the phonemic and typographic level. Once we have recognized the diagram as an iconic sign, too, the presence of iconicity in literature becomes pervasive.

A large number of iconic studies of literature formed an integral part of books on stylistics. Already Spitzer had discussed iconic aspects in some of his stylistic studies, notably in *Linguistics and literary history* (1948), as did Davie (1955), Ullmann (1964), Hollander (1975), Epstein (1975), and Leech and Short (1981). Wimsatt (1976) made a strong plea for more research along iconic lines. Nänny (1986) offered an early survey of iconic aspects of literary texts. Attridge (1982: 287–295) studied iconic functions of poetic rhythms; Cureton (1980, 1986) analyzed the poetry of e. e. cummings from an iconic point of view. Anderson (1998) has presented the most comprehensive survey of iconic features in literary texts so far. Important recent studies of iconicity in literature can be found in the publications that have resulted from the international conferences on 'Iconicity in language and literature' (see the series edited by Nänny and Fischer, 1999; Fischer and Nänny, 2001; Müller and Fischer, 2003; Maeder *et al.,* 2005); evidence for this entry is partly based on the articles collected there.

Interpretation

Especially in literature, language has a surplus of meaning and works "at full stretch" (Nowottny, 1962: 85) by being 'hypersemanticized' (Cureton, 1980: 319) and consisting in a mixture of 'digital' and 'analogical' coding (Bernhart, 1977: 87); therefore, the perception of iconic features depends on the reader's awareness and readiness to recognize, so to speak, the analogical structure behind the digital surface form. As with metaphor, the awareness of iconicity is dependent on the recognition of similarity. Although texts have a range of potential iconicity, this is merely latent. As Givón (1985: 190) writes, "the notion of 'similarity' between two entities requires the *consciousness* of similarity on the part of some cognizing mind." Hence, iconicity, like beauty, is in the eye of the beholder: the perception of imitative form depends on the reader's capacity to see connections, to perceive similarities between the meaning of a sign or text and the formal means used for its expression.

However, not all iconicity is of the same degree. Icons may be divided into 'transparent' and 'translucent' ones (Pateman, 1986). That is, transparent icons are immediately recognizable (these often concern 'images'), whereas translucent ones (usually the more abstract diagrams) need a more careful scrutiny and some imagination. Thus, the transparent icon may be compared to an (explicit) simile, whereas the translucent icon is more like an (implicit) metaphor. In both cases, the reader or hearer is helped by the fact that iconicity is 'foregrounded.' As Haiman writes (*see* **Iconicity**): "The fundamental iconic nature of markedness is a virtual cliché: marked form corresponds to marked meaning."

The question of whether an iconic feature, be it imagic or diagrammatic, is the result of chance or of the poet's design has little relevance. What is important is that a similarity between form and meaning may be perceived intersubjectively. It is important to recognize that iconicity in literature is in the main semantically motivated. The semantic content of the verbal unit or its context has to activate and focus the normally latent mimetic potential. So most iconic interpretation moves from meaning to its formal miming (with the possible exception of 'phonetic metaphors' discussed later), although it is, of course, the form that provides the impetus. What is generally true of any sign is also true of the icon: the meaning of a sign is not fully contained within it but arises only in its interpretation. In short, an iconic dimension will only appear if the meaning of the textual passage is compatible with it. Because the recognition of iconicity is via the mind of the hearer/reader, it also must be clear that the categories of image and diagram are not always clear-cut. Although the imagic icon seems closer to 'reality,' it is still always an abstraction of it. In the diagrammatic icon, the similarity is only in the mapping, the signs themselves no longer reflect any actual features of the referents.

Iconicity in Poetry, Prose, Drama

It may be said that in terms of literary genres the presence of iconicity is highest in poetry, for poetry allows the most complex and innovative use of language in terms of sound and space (typography). According to one important literary tradition even, the Mallarmé-Valéry version of what Roland Barthes called 'Cratylism,' the mimetic or iconic virtue of

language is an especial privilege of poetry: it constitutes the poetic function proper and is seen as a compensation for and defiance of the arbitrariness of the sign. Prose, however, whether descriptive or narrative, offers a wide potential of iconic signification too. Literary works whose narrative is organized by means of the spatial order of a journey or the temporal sequence of a chronology are sequential diagrammatic icons of a comprehensive kind. Drama, being a literary genre that directly mirrors meaning by visible and audible action, gestures, costumes and stage-scenery provides fewer opportunities for the application of verbal iconic functions. Its relative lack of iconicity can perhaps also be explained by the fact that there is not enough time for the audience to grasp its effect; this is particularly true of diagrammatic icons. However, it is well known that, for instance, Shakespeare's plays are heavily iconic.

Imagic Iconicity

The Sound Level

The use of **onomatopoeia** (i.e., acoustic iconicity) and **sound symbolism** in literary texts, especially poetry, is widespread and common. A famous, often quoted example can be found in Lord Tennyson's *The princess* (vii, 202–203):

> The moan of doves in immemorial elms
> And murmuring of innumerable bees

The repetition of the nasals /m/ and /n/ in these two lines (12 occurrences!) suggests the continuously humming sound of "innumerable bees." All the words of the excerpt are, semiotically speaking, symbols by definition, except possibly 'murmur.' But most of them share the hypo-iconic quality of the onomatopoeic image. Thus, J. C. Ransom's famous parodic rendering of the second line as "the murdering of innumerable beeves" is beside the point because in this version there is no longer any miming of meaning: beeves do not hum.

Another interesting passage occurs in William Wordsworth's 'An evening walk' (ll. 143–150):

> How **b**usy the **e**normous hive with**in**,
> While Echo da**ll**ies with the va**r**ious **d**in
> **S**ome, hardl**y** heard their chi**s**sel's **c**linking **s**ound,
> **T**oil, **s**mall as **p**igmies, **in** the gu**lph** **p**rofound;
> **S**ome, **d**im betwe**en** th'aere**a**l **c**liffs **d**escr**y**ed,
> O'erwalk the viewless **p**lank **f**rom side to side;
> These by the **p**ale-blue **r**ocks that **c**easeless **r**ing
> Glad **f**rom their ai**r**y ba**s**kets ha**ng** and **s**ing.

Throughout this excerpt the high, bright, tense, and continuous sounds (given in bold) made by the clinking chisels in a Welsh slate quarry are onomatopoeically rendered by means of a repetition of the relatively high vowels /I/ and /i/ and the fortis plosives /t/, /p/, and /k/, in combination with sharp voiceless fricatives: /s/, /θ/, /f/, and 'singing' nasal and liquid continuants such as, /n/, /m/, /ŋ/, /r/, and /l/.

Onomatopoeia and sound symbolism are not separate phenomena but, rather, form a continuum. Onomatopoeia usually refers to complete acoustic signs, whereas the term sound symbolism is often preserved for **phonaesthemes**, i.e., iconic phonemes or phoneme clusters within the word. The above examples are closer to sound symbolism. A good example of a purer use of onomatopoeia is Eve Merriam's poem 'Weather.' Both onomatopoeia and sound symbolism are affected by the limitations of the phonological system of each individual language, but, in addition, sound symbolism is also influenced by language conventions (many phonaesthemes may be the product of endophoric rather than exophoric icons, cf. A. Fischer, 1999) and by social and cultural attitudes within a speech community. (For a list of sound symbolic icons. An interesting reference to the literary-critical use of sound symbolism is found in a passage from Alexander Pope's *An essay on criticism* (ll. 365–371), whose famous first line explicitly postulates an iconic connection between sound and meaning, which it exemplifies in the succeeding lines:

> The *Sound* must seem an *Echo* to the *Sense*
> *Soft* is the Strain when *Zephyr* gently blows,
> And the *smooth Stream* in *smoother Numbers* flows;
> But when loud Surges lash the sounding Shore,
> The *hoarse*, *rough Verse* shou'd like the *Torrent* roar:
> When *Ajax* strives some Rock's vast Weight to throw,
> The Line too *labours*, and the Words move *slow*.

Thus, in the first three lines the heavy accumulation of fricatives and nasals/liquids reinforces the idea of soft breezes and murmuring streams and echoes the idea of smoothness. Sound symbolism may also work syllabically or across the word, as is clear from the last two lines in the extract from Pope, where Ajax's labor is described in monosyllabic words with awkward consonant clusters either as part of the word ('Aja**x**,' '**str**ive,' '**thr**ow'), or across the word (Aja**x-str**, ro**ck's-v**, va**st-w**, wo**rds-m**).

The Visual Level

Alphabetic letters whose outlines mirror the contours of objects represent iconic images in the normal, visual understanding of the word 'image.' Examples of such letter-icons can be found in Shakespeare's reference to the circular Globe Theatre by the letter-metaphor "this wooden O" (*Henry V*, 'Prologue,'

l. 13) or in John Donne's use of the uppercase letter 'A' as an icon of what a pair of contemporary compasses looked like in "A valediction: forbidding mourning" (ll. 25–26): "If they be two, they are two so/**A**s stiff twin compasses are two." In *Absalom and Achitophel* (Part II, ll. 457–463) John Dryden uses the capital letter 'O' as a translucent icon for the corpulence of the Irish poet Thomas Shadwell, whom he gives the round biblical name 'Og.' A large number of letter-icons is also found in concrete poetry and particularly in the poetry of e. e. cummings, who uses the letters 'O'/'o' for the moon in his 'mOOn Over tOwns mOOn' (*CP* 383) or for a pair of eyes in "l oo k-" ('i will be,' *CP* 195).

Visual outlines of objects have often been created by the typography of **pattern poems** in order to suggest an iconic image of the object the text refers to (wing, flask, cross). The tradition of shaped poems goes back to the ancient Greeks and has had revivals in the Middle Ages, Renaissance, 17th and 20th century. George Herbert's poem 'The altar,' whose boundary evokes a classical altar, and his 'Easter wings' offer famous typographic icons. In modern times, a number of visual or concrete poems have iconic contours of objects: poets such as Apollinaire, the futurists (e.g., Marinetti), J. Hollander, E. Morgan, and many others have written shape poems.

Typographic iconicity may also be conveyed by absence rather than presence. Wolf (2005) shows how **blanks** can be used to suggest silence, as in this short poem 'Schweigen' ('Silence') by Eugen Gomringer:

schweigen schweigen schweigen
schweigen schweigen schweigen
schweigen schweigen
schweigen schweigen schweigen
schweigen schweigen schweigen

Another example of a meaningful blank or white line may be found in Emily Dickinson's poem 'Our lives are Swiss,' in which the blank line between the two stanzas suggests the white "solemn alps" between Switzerland and Italy.

Diagrammatic Iconicity

The Sound Level

Among the most frequent iconic diagrams used in poetry are **rhythm** and **meter**. As is all too familiar, poets have reinforced meaning through sound by controlling the speed and movement of their lines. They do this not only by their selection and arrangement of vowels and consonants, their disposition of pauses, but also by their choice and use of meter and rhythm. This enables poets to express feelings iconically (such as mourning and joy) but also slow and fast movements generally, for instance, galloping in Tennyson's 'The charge of the light brigade.' Conventional poetic metrics may be put in the service of iconicity as well. A somewhat unusual iconic use of the metrical mould of the heroic couplet can be found in Dryden's 'To the Memory of Mr Oldham,' ll. 3–4:

For sure our Souls were near ally'd; and thine
Cast in the same Poetick mould with mine.

The 'Souls' of the deceased young poet Oldham and of the older poet Dryden are actually and formally combined in the mould of the same couplet here (additionally foregrounded by the fact that 'mine' and 'thine' rhyme). But in order to emphasize his view that Oldham was a rougher poet, Dryden makes the second line, representing Oldham's line ('thine/Cast'), somewhat irregular (by means of a trochaic beginning) and less mellifluous (because of five voiceless plosives: **Cas**t, **po**et**ick**).

The repetition of sounds by means of **assonance**, **rhyme**, and **alliteration** may serve diagrammatic purposes. In the passage from Wordsworth's 'An Evening Walk' quoted earlier, the echoing of sounds, "Echo dallies with the various din," made by the clinking chisels is diagrammatically rendered by means of the repetition of the sharp and brief /I/ sounds. Quite generally, echoes are often diagrammatically mimed by a repetition of sounds and words. This is done, for instance, in Wordsworth's lines from '"Yes! It was the mountain Echo"' (ll. 1–4):

YES, it was the m**oun**tain Echo,
Solitary, clear, prof**ound**,
Answering to the sh**ou**ting Cuckoo,
Giving to her s**ound** for s**ound**!

In general, sound repetition foregrounds the phonetic link between two signs thereby foregrounding also a semantic link. The link only works when it is marked; in other words, in poems in which the use of rhyme or alliteration is conventional or follows a conventional scheme, the devices in question do not normally serve an iconic function (cf. Hollander, 1975: 121). Although rhyme usually works on the phonetic level, it has to be noted that rhyme may also work typographically, when poets make use of 'eye-rhymes.'

Most rhymes are based on a combination of phonic similarity or identity and semantic difference. As the poetic (nonconventional) device of rhyme links words in a nonsyntactic way, it may produce new semantic equations and correlations. Perfect

single rhymes, for instance, may be icons of resemblance or unity (cf. the 'thine/mine' rhyme in the couplet from Dryden, discussed earlier), whereas the dissonance of imperfect single rhymes may diagrammatically express disorder, dissimilarity, inaccuracy or even negation, but also doubt and uncertainty. For instance, in 'The first book of Statius his Thebais' (ll. 115–117), Pope makes use of an off-rhyme ('bear'/'prepare' – 'War') to suggest discord ('mutual Hate and War'):

> Go, and a Parent's heavy Curses bear;
> Break all the Bonds of Nature, and prepare
> Their kindred Souls to mutual Hate and War.

The off-rhyme also "Breaks the Bonds" of the pervasive pattern of the dominant heroic couplet. In Shakespeare's *Pericles*, (I.i.45–46),

> For death remembered should be like a mirror,
> Who tells us life's but breath, to trust is error.

The off-rhyme 'mirror/error' emphasizes the semantic 'error' by phonetic means.

Rhyme may also serve as a **phonetic metaphor** linking one sign to another sign, which is left unexpressed and is semantically unrelated, purely by its sound, and thus forcing a new connotation on the sign or creating irony through distance. Peter Howard made use of this to great effect in his poem 'A poppy,' in which he subliminally links words for flowers ('carnation,' 'violets,' 'samphire') with words related to 'war' (carnage, violence, gunfire), ending the poem with generals who were awarded 'petals.' The whole poem, which can only really be appreciated two-dimensionally, is an assemblage of iconic means in its use of colors, fonts, and (temporal) spacing.

Variations in **rhyme schemes** also may assume various iconic tasks such as indicating change and fragmentation. Symmetrical schemes may serve as iconic diagrams of an embrace, a frame or imprisonment, whereas a disruption of the rhyme scheme by non-rhymes may suggest the idea of uniqueness or solitariness. The three rhymes that characterize a triplet may diagrammatically suggest the number three (as in Dryden's 'To the pious memory of Mrs Anne Killigrew' [ll. 41–43]), but also circularity, centering, extension, excess, and continuity. In Donne's poem 'Woman's constancy' (from *Songs and sonnets*, ll. 5–11), the disruption of the rhyme scheme iconically reinforces the (hypothetical) change in the relationship between the speaker and his lover. In Shelley's sonnet 'Ozymandias,' the idea of fragmentation is suggested by a broken rhyme scheme. In a passage from 'The arrival of Ulysses in Ithaca' (ll. 53–55), Pope diagrammatically uses the off-rhyme of the third line of a triplet (which also breaks the scheme of rhyming couplets) to express 'solitary'-ness:

> Mean while *Ulysses* in his Country lay,
> Releas'd from Sleep; and round him might survey
> The solitary Shore, and rowling Sea.

The Visual Level

Ever since poetry was produced as printed text, poets have made use of the possibilities that print offered, such as differences in font, size of letters, spacing, color, special punctuation, etc. A prominent and useful iconic tool in the hands of poets is the manipulation of **lineation**. As with rhyme, both single lines but also variations in conventional lineation schemes may be used with iconic effect, suggesting size, distance, change etc. In his 'erosive poem' 'Archives,' Edwin Morgan presents an iconic diagram of historical attrition by the gradual fading out of lines until they become illegible. In e. e. cummings's poem 'l(a' (from *95 poems*), the lean shape of this text (most lines consist of one or two letters) suggests the outline of the number 1, the (al)oneness of the speaker as well as the pattern made by the solitary falling leaf.

Gradually, longer lines may offer a perfect diagrammatic icon of increase or growth as, for example, in Dryden's satirical characterization of Sir Fopling in his 'Epilogue to *The man of mode*' (ll. 19–22):

> His bulky folly gathers as it goes,
> And, rolling o'er you, like a Snow-ball growes.
> His various modes from various Fathers follow,
> One taught the Toss, and one the new *French* Wallow.

Increasing line-length mirrors the snow-balling of Sir Fopling's "bulky folly," steadily gathering weight, whereas the sixteen 'o/O's' of the passage present iconic images of a "rolling . . . Snow-ball" bowling down the four lines. By contrast, gradually shorter lines may function as iconic diagrams of decrease and decline. In the *Prelude* (Bk. III, ll. 10–12), Wordsworth uses line-shortening to indicate the sucking or contracting force of an eddy:

> The place, as we approached, seemed more and more
> To have an eddy's force, and sucked us in
> More eagerly at every step we took.

A well-known classic example of the use of the downward sequence of lines on the page as an icon of falling, is Milton's description of the fall of Satan in Book I of *Paradise lost* (ll. 740–746). By strategically placing line breaks, Milton uses a kind of imitative form for Satan's fall. Increasing and decreasing line length may also be combined: in T. S. Eliot's 'The love song of J. Alfred Prufrock,' the steady

growth in lines 45–48, followed by diminishing lines in the next stanza, iconically shows the way in which the life and decisions of the speaker's younger days 'reverse' (l. 58) now that he is experienced and coming nearer his life's end.

The overall lineation of a poem may also function as a diagrammatic icon of a speaker's condition. Robert Herrick's 'A Bacchanalian Verse' (first stanza):

> DRinke up
> Your Cup,
> But not spill Wine;
> For if you
> Do,
> 'Tis an ill signe;

expresses a state of drunkenness by the irregularity and staccato of lineation, reinforced by strong enjambment.

The relative (visual) length or shortness of a single line may diagrammatically reflect the semantic content of the line. A classic example is found in Pope's *An essay on criticism* (ll. 355–356), in which the second verse of the couplet mirrors the "slow length" of a snake iconically by an alexandrine whose extra foot prolongs the line:

> A *needless Alexandrine* ends the Song,
> That like a wounded Snake, drags its slow length along.

The remarkable length of the first line of Dickinson's poem 764 metaphorically refers to the premonitory long shadow cast by the setting sun:

> Presentiment – is that long Shadow – on the Lawn –
> Indicative that Suns go down –

An example of a short line expressing diminution or absence can be found in Pope's 'Moral essays: epistle III. to Allen Lord Bathurst' (ll. 281–282):

> Blush, Grandeur, blush! proud Courts, withdraw your blaze!
> Ye little Stars! hide your diminished rays.

The 'blaze' of 'Grandeur' and 'proud Courts' is set off in a prominently long line against the weakly shining 'little Stars' with their 'diminished rays.'

The manipulation of **line breaks** or line endings, whether end-stopped or run-on lines (enjambments), is an important part of the poet's craft. Inevitably, it often assumes iconic force too. In Ted Hughes's 'Second glance at a jaguar' (ll. 16–17), the jaguar's walking back and forth and turning corners all the time is iconically rendered by the way the pertinent descriptive line in his poem breaks:

> At every stride he has to turn a corner
> In himself and correct it . . .

The line-break immediately after "turn a corner" reinforces the jaguar's turning "in himself."

Poets have also made frequent iconic use of the **stanza-break** in order to mark hollowness or openness but also a barrier or separation. In his 'Lines on a young lady's photograph album' (*The less deceived*, ll. 13–14), Philip Larkin makes an impressive iconic use of this between stanzas 7 and 8:

> We know *what was*
> Won't call on us to justify
> Our grief, however hard we yowl across

> The gap from eye to page. So I am left
> To mourn (without a chance of consequence)

The Structural Level: Morphology

Morphological iconicity based on word structure appears often in natural language and is also frequent in literary texts. **Reduplication,** or the consecutive repetition of a morpheme, bound or free, is used in both (and indeed very common in relatively 'new' languages such as Pidgins and Creoles, cf. Kouwenberg, 2003) to indicate the repetition of an action, a frequentative sound or activity (as in 'murmur,' used in Tennyson's line earlier), plurality, intensity or continuity. James Joyce relies on it frequently in both *Ulysses* and *Finnegans wake*, as in the line, "[h]uggermugger in corners. Slop about in slipper-slappers for fear he'd wake" (*Ulysses*, The 'Hades' episode), in which reduplication is used (together with ablaut) as a frequentative and intensifier. Another device resorted to by Joyce is the **blending** of two free morphemes into one word in order to suggest simultaneity or 'oneness'; thus, in the same chapter, we find new lexicalizations such as "silkhatted head," "nose whiteflattened," "craped knocker" (i.e., a knocker "draped with crape").

Partial repetition occurs in **paronomasia,** which involves a similarity in sound between etymologically unconnected words whereby the formal correspondence suggests a semantic connection, as in this line from Shakespeare's *Romeo and Juliet* (III.iv.8): "These times of *woe* afford no times to *woo*" (italics added). A similar example can be found in Donne's *Devotions* (from the 'Seventeenth meditation'): where the phrase "for whom the bell tols"/ "it tols for him/mee/thee" occurs repeatedly, but is transformed at one point into "this bell that tels mee," showing both the urgency of its 'tolling' and what it has to 'tell' us. In most cases, as here, the paronomasia is foregrounded by further repetition of words or of structure. In like manner, the repetition of words by varying their inflexional morphemes (**polyptoton**) or derivational ones (**paronymy**) may serve iconic

ends. The line from *Richard II* (V.v.49), "I wasted time, and now doth time waste me," emphasizes, by the use of the past and present forms of the same verb, Richard's own earlier responsibility for his present state. Donne, in the 'Meditation' quoted earlier, uses the words 'translated,' 'translators' and 'translation' all within the same sentence in order to emphasize the constant 'translation' (i.e., 'transferal') of one action onto the next.

In general, the **repetition** of a word is one of the basic tools of the rhetorician's trade. Thus, the iteration of adverbs such as 'again' or 'oft(en)' performatively reinforces their meaning. This is done, for instance, at the beginning of Wordsworth's 'Tintern Abbey' (ll. 1–15) where 'again' is repeated four times, or in Coleridge's 'Frost at midnight' (ll. 23–26) where 'oft' is repeated three times. A similar iconic effect is achieved in Wordsworth's 'echoes loud / Redoubled and redoubled' (from 'There was a boy,' ll. 14–15), with the repetition enacting the echo. G. M. Hopkins's repetition of 'trod' in "Generations have trod, have trod, have trod; / And all is seared with trade; bleared, smeared with / toil" (from 'God's Grandeur,' ll. 5–6) stresses the monotony of generations of toil, which is further enhanced by the paronomasia in "bleared, smeared." In Wordsworth's 'Elegiac stanzas' (ll. 5–6), the repetition of words reinforces the ideas of both continuity and similarity: "So pure the sky, so quiet was the air! / So like, so very like, was day to day."

Combined with decreasing length, the iteration of a word may present an icon of acceleration as in J. Masters's *Bhowani Junction* (chap. 28):

> Pater [the engine-driver] tugged the whistle-cord again and [. . .]. Whooof! the platform began to slide back. [. . .] Whooof! I saw the Stationmaster writing in a notebook; whoof – a man could still walk beside the train; whoof – he'd have to run; whoof – run fast; whoof, whoof, whoof, whoof!

Masters reenacts the acceleration of a departing steam-engine by means of gradually decreasing phrases and word-length that he puts between the repeated acoustic icons 'whoof.'

In many cases the position of the repeated sign (or structure) adds to the effect of this iconic device; this, however, belongs more properly in the next section, syntax.

The Structural Level: Syntax

The repetition of a word or structure may be more foregrounded by giving the repeated sign the same initial or final position (**anaphora** and **epistrophe** respectively) or a clearly opposite position (**anadiplosis**). Thus, in Shakespeare's *The merchant of Venice* (III.iii.4–5):

> I'll have my bond, speak not against my bond, –
> I have sworn an oath, that I will have my bond

The repeated end-position of 'bond' emphasizes Shylock's fixation on the letter of the bond. In contrast, in the medieval poem 'The pearl,' the *last* word of each stanza is repeated in the *first* line of the next stanza: "To bye hym a perle wat three mascelle three. // This makele three perle, þat bo three t is dere" (ll. 732–733), in order to mime the perfect *round*ness of the 'immaculate pearl.' Herbert uses a very similar device in his poem 'A wreath' to suggest the way the wreath is woven together. Leech and Short (1981: 219) show how Joseph Conrad in his novel *The secret agent*, uses a similar 'chaining' device to suggest the halting perception of one of its characters.

Position may also be used without repetition, when the lexical content of the word itself reflects its position. Thus, the word 'end' is often put at the end of a line, passage or text. An early example is offered by Herbert's poem 'Paradise,' which ends on the capitalized 'END.' In Wordsworth's *Prelude* (Bk. VI, ll. 570–572), there is a passage that ends on the word 'end' and in which the words 'first' and 'midst' are also iconically positioned:

> Characters of the great Apocalypse,
> The types and symbols of Eternity,
> Of first, and last, and midst, and without end.

By manipulating the sequence of textual elements, writers may embody meaning in verbal form. A natural form of iconicity occurs when the signs are used in such a way that their order reflects the **chronological** order of the actions referred to. Poets also use sequencing to suggest **distance** or **proximity** (both temporal and spatial). They may foreground proximity by putting two (semantically or syntactically unrelated) signs next to one another, and distance by putting semantically or syntactically connected items at the opposite extremes of a line. Wordsworth's poetry offers an example of the latter in his *Prelude* (Bk. V, ll. 79–80), where he describes the dream of an Arab who had

> . . . underneath one arm
> A stone, and in the opposite hand, a shell.

'Stone' and 'shell,' are placed at the opposite ends of the line, reflecting left-hand and right-hand position.

Another way in which syntax may be manipulated is by the use of **ellipsis** and structural **parallelism**. Charles Dickens uses ellipsis as well as parallel structure (and lexical repetition) at the beginning of *Bleak House*,

> Fog everywhere. Fog up the river, where it flows . . .; fog down the river, where it rolls . . . Fog on the Essex Marshes, fog on the Kentish heights. Fog creeping into . . .; fog lying out on . . .; fog drooping on . . . Fog in the eyes and throats of . . .; fog in the stem and bowl of . . .

The ellipsis of finite verbal forms in the main clauses, and the repetition of the same structural patterns (prepositional phrases, *-ing* forms, 'where'-clauses) present a syntactic icon of London as "a world of stasis, devoid of real action" (Müller, 1999: 396). Another example of this can be found in Christina Rossetti's 'Sleeping at last,' which has not a single finite verb in the first two stanzas, describing death ("sleeping at last"). Syntactic parallelism together with **asyndeton** (an abrupt sequence of unconnected phrases) may be used as an iconic suggestion of simultaneity, "Women shrieked, cattle bellowed, dogs howled, men ran to and fro . . . " (Sir Walter Scott, *Old mortality,* 1893: 185), a device frequently employed by Dickens, too. Asyndeton is also used to suggest brief, vehement, jerky movements or inner agitation. Samuel Richardson makes frequent use of this to convey extreme emotional states in his novels *Pamela* and *Clarissa*. In contrast, **polysyndeton** (the repeated use of a connector), may suggest weariness, or something long drawn out as in *Macbeth*'s (V.v.19–20): "To-morrow, and to-morrow, and to-morrow,/ Creeps in this petty pace from day to day." Syntactic **subordination** may serve as a diagrammatic icon of hierarchy, of narrative distinction between primary, secondary and tertiary matters as, e.g., in Henry Fielding's *Tom Jones*, where the syntactic structure is a *mise-en-abyme* of the structure of the whole novel (cf. Müller, 1999: 402–406).

The degree of **transitivity** of a construction used may have an effect on the meaning of the text. We saw above that the absence of finite verbs suggests stasis. In a similar way the use of intransitive verbs may reflect nonfinality. In Raymond Chandler's *The little sister*, the following description occurs (Penguin ed., 49): "I collapsed on the floor. The door opened. A key rattled. The door closed. The key turned. Silence." The use of intransitive, or indeed ergative, verbs gives the atmosphere an air of suspension. No agent is mentioned, the effect is given but the cause remains unknown. Transitivity is also connected to the choice of subject. Animate subjects are highly transitive, while inanimate subjects distance the reader from the text, making him feel less involved. Jane Austen was fond of using inanimate subjects, which created the distance necessary for her irony to work. In chapter 18 of *Emma,* she describes Mrs. Weston's severe disappointment as follows:

> Mrs Weston was exceedingly disappointed – much more disappointed, in fact, than her husband, though *her dependence* on seeing the young man had been so much more sober: but *a sanguine temper*, though for ever *expecting* more good than occurs, does not always *pay* for its hopes by any proportionate depression. *It* soon *flies* over the present failure, and *begins* to hope again. (Italics added)

By using abstract nouns as subjects of verbs, which normally take animate subjects, we are removed from sharing the character's feelings.

A more clearly literary device is the use of **chiasmus**. Chiasmus is a verbal figure of repetition whose second half inverts the order of the elements in the first half: 1–2–3 >< 3–2–1. Obviously, this figure may be used as an iconic diagram for it obeys a certain relational order or arrangement of its constituents. But depending on the meaning an author wants to reinforce, this figure may be interpreted in various ways. To mention just a few, a chiastic arrangement may be seen as a dynamic, circular sequence that returns to its beginning (1>2>3:3>2>1) or as a sequence that inverts its direction (1> 2>3><3<2<1). But the pattern may also be interpreted as a static arrangement of components expressing symmetry, multiple bracketing or centering (1[2[3:3]2]1]) of the inner elements by the outer ones.

A simple example of chiasmus is found in *Macbeth* (I.i.11): The witches' "Fair is foul and foul is fair." This mantric phrase may be seen as an emblem, a *mise-en-abyme* of the plot of the play that starts out fair, deals with a lot of foulness and ends fair again. A chiastic order of letters that iconically reinforce the idea of enclosure is offered by Coleridge in a passage from his 'Frost at midnight' (ll. 51–52), in which the speaker remembers his school days and complains about his prison-like boarding school: "For I was reared/In the great city, pent 'mid cloisters dim." The reversal of the letters in 'mid' and 'dim' presents a small-scale enclosure, perfectly framing the secluded enclosure of the 'cloisters.' A chiasmus of sounds is used by Coleridge in the first line of 'Kubla Khan': "In Xanadu did Kubla Khan/A stately pleasure-dome decree." The chiastic sequence of the accented and unaccented vowels, /z**a:** na d**u: did** k**u:** bla k**a:**n/, may be said to allude to the symmetry of the 'dome.' The palindrome 'did' is the perfect pivot of the whole scheme.

Chiasmus also may be spread over a larger piece of text as in Blake's poem 'A divine image,' in which the 'fearful symmetry' of the divine form of man is iconically expressed across the two stanzas showing both a reversed position of four phrases within the lines as

well as across the lines, making the symmetry even stronger.

Structural chiasmus, making use of the same lexical items or letters, forms a transparent icon. Next to these there are also translucent icons, where the repeated signs are not in strictly reverse positions or where they involve synonyms and antonyms rather than the same sign. In *Soldier's home* (second paragraph), Hemingway uses such a chiasmus as a diagrammatic reflection of inversion, centering and quasi-visual symmetry:

> There is a *picture* which *show*s him on *the Rhine* with two *German girls* and another *corporal*. Krebs and the *corporal* look too big for their uniforms. The *German girls* are not beautiful. *The Rhine* does not *show* in the *picture*. (Italics added)

By looking only at the italicized items and ignoring the surrounding words, we can spot the chiasmus, which, interwoven with the narrative, one would normally not see. It is interesting to note that 'Krebs,' whose name stands at the fulcrum of the inversion, is the German word for crayfish, an animal that is famous for inverting its movement by walking forwards and backwards. This chiasmus functions as a quasi-pictorial verbal frame for the description of the photograph, as well as an emblem for the reversal of the soldier's outlook on life after his experience in the war. A chiasmus may become even more difficult to spot when the repeated elements are no longer lexically the same, as in Hemingway's 'Chapter IV' from *In our time*. To see the chiasmus, we have given the repeated elements in italics and highlighted the repeated *synonymous* expressions by putting them in bold.

> It was a *frightfully* hot day. We'd jammed an *absolutely perfect* ***barricade*** across the bridge. It was simply priceless. A big old wrought-iron grating from the front of a house. Too heavy to lift and you could ***shoot*** through it and they would have *to* ***climb*** *over it*. It was **absolutely topping.** They tried *to* ***get*** *over it*, and we ***potted*** them from forty yards. They rushed it, and officers came out alone and worked on it. It was an *absolutely perfect* ***obstacle***. Their officers were very fine. We were *frightfully* put out when we heard the flank had gone, and we had to fall back.

This chiastic order is an icon of a symmetrical opposition of enemy troops on the two sides of a bridge, across which the obstacle of a "big old wrought-iron grating" has been put. The chiastically centralized "absolutely topping" reflects the 'top' of the bridge, the soldiers' main aim, which both sides in the end do not reach/hold.

The Semantic Level

Since semiotics is concerned with the *interpretation* of signs, iconicity as a subfield is intimately connected with semantics. As was stated previously, a sign functions as an icon only via the perception of a language user: without interpretation there is no icon. The examples that have been discussed so far all rely heavily on form, it is the formal internal structure, the repetition of forms, or the way forms are ordered which suggest an iconic interpretation, with the language user perceiving some similarity with reality (exophoric) or between two forms (endophoric). Some iconic structures rely more heavily on meaning. The prime example is **metaphor**, which properly belongs to this section, since the similarity in form only occurs as the *result* of a perceived similarity in meaning. Some of the structures discussed earlier also rely more heavily on semantics, as is the case with chiastic constructions that are not mere formal repetitions but involve synonyms and antonyms. It is clear in such cases that without prior interpretation of these items there can be no recognition of a particular structural ordering. The same would be true for a syntactic parallelism that employs different lexical items, as in the quotation from Chandler earlier: "The door opened. A key rattled. The door closed. The key turned." One needs to know the meaning of those items in order to see that each sentence involves a subject and an ergative verb. Also the examples discussed in the previous section, where signs meaning 'end' are placed at the end, are only possible if one knows the meaning of the sign beforehand; the *form* of the sign does not contribute in any way to its iconicity. It is clear then that knowledge of the meaning of a sign is a vital part of all iconic recognition, and that in quite a few cases form only marginally contributes.

The Discourse and Narrative Level

A literary text as a whole also may be an icon of what it is about. Bolinger (1980: 18) notes a direct relation between the overall size or intricacy of the linguistic text and the ideas that the text expresses. To give a few examples: The highly idiosyncratic form, in terms of genre and style, of Hopkins's 'curtal sonnet' 'Pied beauty' mirrors the most highly individualized 'inscape' of God and of his creation, which the poem performatively celebrates. The extreme briefness of Ezra Pound's poem 'In a station of the metro'

> The apparition of these faces in the crowd;
> Petals on a wet, black bough.

iconically reflects the instantaneous associative perception expressed in it. The size of Melville's *Moby Dick* is an iconic image of its huge subject, the whale. In chapter 104, Melville explicitly refers to the iconic relationship between his "mighty theme" and the bulk of his "mighty book." Joyce's *Finnegans wake*, by contrast, may be interpreted as a diagrammatic icon of dreaming. Quite generally, the metonymic, additive structuring of realistic texts are an effort to offer icons of visible reality. As W. Bagehot observed, Dickens's complex and teeming novels reflect the unstructured richness of a modern metropolis, which also finds its daily icon in the newspaper front page. Similarly, both Joyce's *Ulysses* and T. S. Eliot's *The waste land* are, on one level at least, structural icons of city-life in which, according to Pound (1921: 110), "the visual impressions succeed each other, overlap, overcross, they are 'cinematographic.'"

Hemingway uses a chiastic arrangement in the short story *Indian camp* on the level of narrative to reflect the circularity of the cycle of day and night, birth and death so central to the story. The narrative of whole novels may also be organized chiastically as Ljungberg (2001) has shown with respect to the fiction of Margaret Atwood. Thus, *The robber bride* (1993) has a chiastic narrative order: it is organized by a frame narrative containing 'three different narratives, each of which forms a kind of palindrome in time and space' (ibid., 357), which has several iconic narrative functions.

In his first novel *Ochered'* ('The queue' 1985), the Russian writer Vladimir Sorokin uses a (typographic) structure that is defined by icons of space and time. This novel, a polylogue comprised entirely of snatches of conversation, mostly single words and phrases, has no narrator and is about people standing in a queue, waiting for roll-calls and passing their time by solving crossword puzzles, reading aloud notices from the newspaper, or discussing recent events. The excessive length of the queue is iconically rendered by the length of the printed column of mostly brief utterances that make up the whole novel, the repetition of identical types of expressions, the linear sequence of names. By creating the impression that the portrayal of depicted time (42 hours) seemingly converges with the time of depiction, the passage of time is also rendered iconically. The portrayal of a sexual act takes 18 pages and the absence of speech, silence, or sleep, are typographically reflected by white pages (cf. Ohme, 2003).

Degrees of iconicity also may be discerned in the narrative representation of speech and point of view. The use of indirect speech, for instance, is less iconic than free indirect speech and even less than written dialogue, which is most mimetic of real speech. Interior monologue (stream of consciousness) or digressiveness in narration is also highly iconic in its associative rendering of mental processes. Wolf (2001) shows that in the Romantic period landscape description began to be presented as paintings that emanated from the point of view of an involved viewer. In a similar way, Tabakowska (1999) shows how the relation between text and conceptual structure can be motivated by the perception of chronology or spacing (**perceptual iconicity**), but also by the perceiver's order of knowledge (**experiential iconicity**).

Iconicity, Sign Language

S Wilcox, University of New Mexico, Albuquerque, NM, USA

'Iconicity' is a term coined by C. W. Morris (1901–1979; *see* **Morris, Charles (1901–1979)**) that designates the measure of similarity between a sign and the object to which it refers (Bussmann, 1996: 215). The nature of this relation has been discussed and debated since antiquity. Jakobson (1990) traces the crucial question of iconicity's role in language, whether language attaches form to content by nature (*physei*) or by convention (*thesei*), to Plato's dialogue *Cratylus*. Socrates, the moderator of this debate, tends to think that representation by similarity is superior to the use of arbitrary signs but in the end tends to accept the position that conventionality plays a major role in language.

In American linguistics, Dwight Whitney (1827–1894; *see* **Whitney, William Dwight (1827–1894)**) also came down on the side of convention and was instrumental in a worldwide acceptance of the definition of language as a system of arbitrary and conventional signs. Perhaps the most influential linguist on this topic was Ferdinand de Saussure (1857–1913; *see* **Saussure, Ferdinand (-Mongin) de (1857–1913)**), who, following Whitney, maintained that "the bond uniting the signans with the signatum is arbitrary" (Saussure, 1916: 67).

Linguists in the functionalist and cognitive schools often regard iconicity as an essential feature of language (Haiman, 1985). Givón's iconic imperative states that "all other things being equal, a coded

Iconicity: Theory

F Merrell, Purdue University, West Lafayette, IN, USA

Iconicity Precedes Conceptual Signs

Starkly put, iconicity comes about through some resemblance between something and something else, and a sign is iconic if there is some resemblance between that which represents and that which is represented. But problems immediately arise, and they can be properly addressed only with some qualification of a sign as iconic.

Charles Sanders Peirce's semiotic theory in its most basic form specifies three different sign types – icons, indices, and symbols – and these are correlated with his three categories of the world's processes and of mental processes, Firstness, Secondness, and Thirdness. These three categories are briefly defined as follows:

1. Firstness *is* what *is*, and has not (yet) entered into any interrelation with any *other*. In this sense, it is no more than possibility. An icon, in and of itself, is a sign of Firstness: it is what it is, insofar as some resemblance between it and something else has not (yet) been foregrounded. (Examples: a triangle as an icon of some mountain, or a cloud formation as an icon of waves breaking when they head toward a beach.) Notice that there is neither foreground nor background: there is no more and no less than that which is.
2. Secondness *is* what *is*, insofar as it bears some interrelation with some *other* that it *is not*, though that interrelation has not (yet) been foregrounded by some potential interpreting agent. Secondness is actuality or existence, whether in the mind or in the physical world. An index as a sign chiefly of Secondness is something interrelated with something else by a physical or presumably 'real' interaction with that something else. (Examples: smoke and fire, a cup and its content, an arrow and what it indicates, or a thermometer and air temperature.) Notice that the interrelation involves interaction that is a matter of causality, contiguity, container–contained, or part–whole. Notice also that the index is a sign of some *particular* existent mental or physical world entity, and does not (yet) evince the idea of a general class of entities of which the sign could potentially be a sign.
3. Thirdness *is* what *is*, insofar as it brings about (mediates) an interrelated interaction between something and something else in the same way that it enters into the same interrelated interaction with that something and that something else. Thirdness entails mediation of something and something else by a third entity, leading to some motivated or otherwise potential or necessary interpretation. A symbolic sign is something that

interrelatedly interacts with something else, such interrelated interaction having been foregrounded by an interpreting agent such that that something (Firstness) and something else (creating Secondness) are brought into interrelated interaction in the same way that the interpreting agent (and hence the interpretation interrelated) interact with that something and something else. (Examples: *x* and a set of variables in algebra, or 'horse' and the organism so named.) Notice that there is no necessary interrelated interaction by resemblance or physical connection, but rather by a convention shared by some community of interpreting agents. Notice that a symbol or sign of Thirdness is a sign of generality, a sign that can be used as if it were standing in for an entire class of entities of which the sign is a sign. Notice, in addition, that the qualification, 'yet,' does not enter into Thirdness or symbolicity, since the triadic nature of the Peircean sign is now in effect. Finally, notice that the term 'interrelation' was introduced with Firstness and the term 'interaction' was introduced with Secondness, and with Thirdness the 'interdependency' of the triadic nature of the sign and of all signs was implied.

Without Iconicity, There Is neither Indexicality nor Symbolicity

Why, in a definition of iconicity, is there any need to introduce indexicality, symbolicity, and Peirce's categories? The answer is, first, because iconicity is by its very nature problematic, as mentioned at the outset. Nelson Goodman (1976b), among a host of scholars, and Peirce (1931–1935: vol. 2, §247; further references to Peirce's six-volume set of papers will be designated CP, with the volume and page number formatted as 2.247, for example) as well, point out that anything can be similar to anything else in some way or other. So the possibilities of iconicity would seem virtually unlimited; hence the question of bringing iconicity to some sort of conceptual order. Second, a sign is an image of that which it images, and thus exists as the idea of some interrelation between image and imaged. But an idea in its most basic, Peirce tells us, cannot be an icon, or more specifically a *pure icon*, except in the sense that it is no more than a possibility, Firstness. A "possibility alone is an Icon purely by virtue of its quality" (CP: 2.276). This is to say, an icon is no more than a quality that has not yet been specified. Strictly speaking, it is (as yet) neither existent nor nonexistent, thus it is no more than the possible content of attention or consciousness on the part of an interpreting agent. Peirce writes that when contemplating a painting, we may "lose the consciousness that it is not the thing, the distinction of the real and the copy disappears, and it is for the moment a pure dream – not any particular existence [Secondness], and yet not general [Thirdness]. At that moment we are contemplating an *icon*" (CP: 3.362). This would be the case of taking a map for the territory mapped, catching a glimpse of McDonalds's Golden Arches and unwittingly watering at the mouth, or noticing a Ku Klux Klan garment and spontaneously clenching our fists. The icon becomes that which is as it is, as if it were both what it is and the actual thing with which it interrelates.

Third, there is the problem of typology. The very idea that anything can resemble anything else in some imagined respect or other apparently throws things into disarray. How can we hope to bring order to the unruly mess? The obvious response is that we can bring order about by specifying a sign *as* a sign *of* a particular sort right here and now (an index, of Secondness), and, more effectively, by generalizing a sign *as* a sign *that* is this sort of sign because it evinces such-and-such a set of properties (a symbol, of Thirdness). This is to imply that the three basic signs as well as the categories cannot be disconnected: remove one leg of the semiotic tripod, and it falls in a heap. It also implies that lines of demarcation between sign types and the categories are fuzzy. This must be the case, for, if we take Peirce's process philosophy at face value, we must concede that everything is always becoming something other than what it was becoming. And finally, it implies that the sign process – the process of specifying and interpreting signs – is cumulative. In other words, in Peirce's words, "every symbol must have, organically attached to it, its Indices of Reaction and its Icons of Qualities" (CP: 5.119). This is because a symbol "is a sign naturally fit to declare that the set of objects which is denoted by whatever set of indices may be in certain ways attached to it is represented by an icon associated with it" (CP: 2.295). So any definition of iconicity necessarily entails the categories, as well as indexicality and symbolicity, and the same must be said of the latter two sign types as well as the former sign type.

Icons Are Necessary for Thought

The Peircean concept of the sign has it that reasoning takes place through iconic signs, whether by way of algebra (CP: 3.376), geometry (CP: 4.447), logic (CP: 4.447–448), or diagrams (CP: 2.282), as well as by resemblances (CP: 2.281) and pure imagery (CP: 4.448). Peirce grounds this idea in his premonition that "where certain relations subsist certain others

are found, and it accordingly requires the exhibition of the relations reasoned within an icon" (CP: 3.363). This is to say that at its roots, all communication is indelibly iconic in nature. Though in and of themselves icons cannot convey information, the only means of directly communicating ideas is *through* icons, and every indirect method of communication must be based on their use (CP: 2.314, 4.554). That is, when communication is indirect, icons exhibit the features of states of some quality or other, indices direct the potential sign interpreter's attention toward what *is* or *happens to be*, and symbols bring thought into the picture, thought engendered by the interpreter in collaboration with the sign. And a genuine sign emerges. It all came about, however, thanks to the icon. Icons, Peirce reiterated time and time again, are more fundamental than are the more developed sorts of signs, and without them those more developed signs could never hope to see the light of day.

Thomas Sebeok (1979: 117–118) critiques the notion that icons are exclusively visual: they can also be auditory, olfactory, gustatory, and tactile. And Umberto Eco (1976: 191–217) argues against the popular assumption that icons are exclusively connected by visual similarity to, or are motivated by, their object. Peirce by no means propagates this obvious penchant for imagery. Given, his notion of iconicity is vaguely related to the Platonic concept of mimesis, but it is expanded, as Aristotle built on Platonic foundations, from the visual to cognitive processes. In fact, Peirce repeatedly argued that logic – another name for semiotic, especially given its mathematical connections and its eminent availability to the knowing intelligence – comes by way of what he called "diagrammatic reasoning" through "abstractive observation" (Kent, 1997). And, one must emphasize, 'diagrammatic reasoning' is iconic through and through. Engaged in the activity of 'diagrammatic reasoning,' the interpreter

> Makes in his imagination a sort of skeleton diagram or outline sketch . . . considers what modifications the hypothetical state of things would require to be made in that picture, and then examines it, that is, *observes* what he has imagined . . . . By such a process, which is at bottom very much like mathematical reasoning we can reach conclusions as to what *would* be true of signs in all [such] cases. (CP: 2.227)

In other words, 'diagrammatic reasoning,' the initial stage of all reasoning and 'the only really fertile reasoning' by use of the faculty of imagination, is fundamentally iconic (CP: 4.571). The ultimate test of this product of imagination is observational, that is, indexical, which leads potentially to a determination of what *would occur* if a contrary-to-fact condition were the case, the *would be* relating that which was imagined to be the consequence of a hypothetical condition. This reasoning process entails *relations*, which, to complete the cycle, are most adequately accessible by means of diagrammatic constructs – that is, icons. The most suitable logic for studying the reasoning process is thus the most richly iconic (Gardner, 1968: 28–59). But this notion of iconicity does not guarantee concrete, visual imagery. On the contrary, thought by way of diagrammatic reasoning involves construction and contemplation of abstract, schematic blueprints, whether in the mind, on paper, or elsewhere, the primary focus of which rests on interconnectedness, not things or patterns, and not essences (CP: 2.282). Indeed, icons are good to think with.

Icons Have at Times Had Bad Publicity

Iconicity, unfortunately, was pushed aside by French semiology and exclusively linguistic concepts of communication, and the bias against iconicity and in favor of textuality (symbolism) continues in present poststructuralist and neopragmatic concerns. This is nowhere more evident than in the beginning of this trend, when Roland Barthes (1968: 10–11) stood Saussure on his head by rendering language the stepmother of semiology, rather than the other way round. On the other side of the Atlantic, the French brand of semiology exerted its early influence in the name of Jonathan Culler (1975: 17) among others, who jettisoned iconicity as more appropriate to the "concern of a philosophical theory of representation than of a linguistic based semiology." Eco (1976: 228) lamented that during the heyday of semiology, this linguistic imperialism created a "dangerous verbocentric dogmatism whereby the dignity of 'language' was conferred only on systems ruled by a double articulation." The same sentiment was evident outside the semiology-structuralist controversy. For example, the radical nominalist Nelson Goodman (1976a: 3–6) charged that iconicity by way of similarity created an unruly jungle that was no sufficient condition for representation. Even topologist René Thom, who was otherwise sympathetic to the semiotic enterprise, disparagingly wrote that the icon is of relatively little interest (1983: 261–271).

On the other side of the ledger, Eco (1976: 192–200) criticized Peirce's notion of iconicity on the grounds that icons are culturally coded by convention more flexibly than Peirce was willing to admit. Eco's argument, however, loses much of its sting, since Peirce attributed a conventional mode of representation to the material icon (CP: 2.276). This mode

is best illustrated in what Peirce calls *hypoicons*: possible signs that function iconically (as *images* by resemblance) indexically (as *diagrams* by some actual connection with that which they resemble), and symbolically (as *metaphors* through linguistic conventions) (CP: 2.276–320). Sebeok (1979: 113–114) compares hypoicons to two pervasive modes of representation in intellectual endeavors: James G. Frazer's magic by similarity and by contact or contagion, and Roman Jakobson's aphasic similarity and contiguity disorders, which derive from Saussure's axes of simultaneity and succession. By integration of Freud's condensation/displacement, Lacan's metaphor/metonymy, and other variations of the age-old theme of association by similarity and contiguity – which Peirce himself occasionally and rather apologetically evoked – this formulation could be extended almost indefinitely. Be that as it may, Peirce's division of hypoicons into images, diagrams, and metaphors once again evokes the categories, Firstness, Secondness and Thirdness. Let us briefly drill in on this theme.

Icons: Always Less Than Pure

Images provoke feelings of something yet unspecified, diagrams bring sensations of something that is other than that which they resemble, and metaphors afford a symbolic or linguistic allusion to something that *interdepends*, *interrelates*, and *interacts* with something else. Here, we find the source of 'diagrammatic thinking.' Here also we find the source of all thinking in iconicity, that which makes way for indexicality and symbolicity to emerge into the light of day, for the interdependent, interrelated interaction of all signs includes sign makers and sign takers. Signs are not merely a matter of what we do with signs, but also what signs do with us. Our semiotic worlds, including ourselves as signifying agents, are never fixed, independent, and autonomous entities. We are all emergent. In concert, we are all always becoming something other than what we were becoming. Since we are in the semiotic universe together, we usually manage to find some degree of balance, harmony, resonance, and consonance. But these are ephemeral islands within the vast ocean of disequilibrium, antagonism, offbeat syncopation, dissonance, and, above all, noise. Semiotic inconsistencies there always were and there always will be. And since we always find ourselves somewhere within our semiotic universe, there is no stepping outside, no ultimate transcendence, no knowing the totality: what we can know is never more than incomplete.

Indeed, ideally we would expect that iconicity, like similarity, enjoys relations of symmetry and reflexivity. This is the symmetry argument (Sebeok, 1976: 128). Actually, icons, good to think with as they emerge and merge into indexicality and symbolicity, are never symmetrical through time (Sonesson, 1994). Peirce's idea of our momentarily taking a painting for what is 'real' is pure iconicity, for sure. But it isn't iconicity *for* us, *for* consciousness (CP: 3.1, 3.362, 4.447, 4.531). When we become conscious *of* icons that are something other, *for* us, and when we acknowledge *that* they are icons of a certain sort because they sport such-and-such a set of characteristics, then those icons have already been navigating along the irreversible, irreflexive, asymmetrical, and transitive stream that inevitably brings on some degree of imbalance, dissonance, or disequilibrium.

Were an icon to evince perfect symmetry, like a sphere, then, granting Eco his say, a mirror image would be no sign at all. But icons, after having become part of thought, are always less than symmetrical. In this case, a mirror image of something less than symmetrical produces an enantiomorph. This is blemished symmetry that, at its most distorted, would put us in Alice's Wonderland. However, our icons are rarely so distorted. And fortunately so for us, for if an icon were complete, and if absolute symmetry prevailed, we would have none other than that map – once evoked by Peirce and Argentine writer Jorge Luis Borges via Josiah Royce – that is coterminous with the territory it presumably maps, such that to traverse the map is virtually the same as exploring the territory. Actually, just as there is never complete knowledge of an ideal symmetrical totality of our semiotic universe, so also there is never total antisymmetry or inconsistency (Bouissac, 1986: 194). We are apparently always floating along the stream, somewhere, between the ideal, well-formed whole, and a vast collection of unruly, unstructured particulars.

Of Mirrors, Triangles, and Tripods: Further Qualification of the Icon

Actually, the notion of mirror-imagery is indelibly binary in character. It is an elaboration on Saussure's metaphor of the signifier and the signified making up a sign, like two sides of a sheet of paper. This simply will not fly. We need triadicity. The triangle has often been evoked as a representation of Peirce's triadic notion of the sign. As the story goes, each corner of the triangle represents a sign component: *Representamen* (comparable to what usually goes as the sign), semiotic *Object* (often called, though somewhat erroneously, the referent of the sign), and *Interpretant* (which includes the sign's interpretation, and also the sign's maker and taker as well). The problem is that the triangle's sides, connecting the corners,

Figure 1 The asymmetrical tripod: Interpretant (*I*), Representamen (*R*), and Object (*O*). Only the central point is absolutely symmetrical.

make up no more than three binary relations. There is no genuine interdependent, interrelated, interactive triadicity.

So, consider a tripod (Figure 1). The Interpretant (*I*) comes into interrelated interaction with and mediates between the Representamen (*R*) and the semiotic Object (*O*) in the same way that *R* and *O* come into interrelated interaction with *I* and with each other. Only the central point, a swirling vortex, pure 'emptiness,' is absolutely symmetrical. But, of course, the point is not *for* mere feeble, fallible mortals: we need something we think we can grasp, namely, *R*s, *O*s, *I*s, and their myriad possible combinations. As a model, the tripod is asymmetrical: it teeters and totters, always tenuously in balance, veering now toward consonance and resonance, now toward dissonance, now threatening to collapse when one of the three legs falters.

But there is a mirror within iconicity. How so? Chiefly because there is the overriding tendency to take an icon – and by extrapolation any sign, for that matter – as just what is, and that is that. This is basically Aristotle's Law of Identity ('*A* is *A*'). If something is *A*, then it cannot be not-*A*. Another way of expressing identity might be '$A \equiv A$,' meaning '*A* is roughly identical to *A*.' If we see the icon and nothing but the icon, then that is all there is. In this sense, putting sentence 1 in Figure 2 in terms of positivity and negativity, we might say that 'The icon is (+) what it is (+),' or: '$+1 \times +1 = +1$.' That seems easy enough. The icon, '+1,' is a simple a sign in the mind. In other words, the icon, or '+1,' is the positive assertion of a thing as what it is. Peirce writes that anything, whether existent or nonexistent, natural or conventional, can be made out to be an icon insofar as it is like the thing iconized (CP: 2.247). Assume that an ant on the beach, while ambulating on the surface of a smooth patch of dry sand, makes a set of squiggles. This, for sure, is a naturally occurring event. Now assume that you look at it and you are able to make out a Winston Churchill caricature. Caricatures are the product of cultural convention. Was there a natural resemblance between the

Figure 2 Iconicity. Interpretant (*I*), Representamen (*R*), and Object (*O*).

squiggles on the sand and Churchill's mug? Apparently. Was your iconizing the squiggles a conventional act? So it would seem. Was the icon a proper iconic sign before you made the connection? No. It was no more than a possible sign. The possible icon was just what it was, without there (as yet) existing any interdependent interrelation between the icon and that which it iconized. Could the icon have emerged as a proper icon without you, the semiotic agent? Hardly. The emergence of iconicity is necessarily *triadic*. Thus sentence 1 in Figure 2 illustrates the sign in the adjacent diagram as a set of connections without the central point or vortex – as was depicted in Figure 1 – that brings about the interdependent, interrelated interaction between Representamen, semiotic Object, and Interpretant – all of which at this point are possible, not actual. However, Peirce tells us in many ways that a genuine sign is not merely what it is. We do not simply sense things as what they are and nothing more than what they are. We sense them in terms of something *other*, something they *are not*. This ushers in Peirce's category Secondness. In this regard, the object of sentence 2 in Figure 2 is not merely what it *is*, but it implies what it is with respect to what, in some form or fashion, it *is not*. In other words, the resemblance is a matter of thought, which abstracts resemblances from nonresemblances (CP: 1.369). By sentence 1 you might assert 'That's Churchill.' It is what it is, positively, and with no other qualification. You are asking your audience to believe your assertion in terms of what the icon is, and apparently nothing more. You have wrapped the object up in

a neat conceptual package and classified it: this is only natural, it would appear. We usually try our best to transform our chaotic world into a sensible world, and in so doing we hardly notice what is actually taking place. And what is taking place? Raw experience. Sentence 1 is incomplete at best, for if you say the object is 'Churchill,' you have already classified it is as something *instead of* something else.

So, we might say in accord with sentence 2, 'The icon is (+) what it is not (−)', or '$+1 \times -1 = -1$'. The icon (+1) is implied by what it is not (−1) as the negation of itself. In other words, a thing, in being what it is not, is '−1'. Negativity accounts for the object of consciousness, just as does positivity. The squiggles in the sand resemble Churchill, yet Churchill's actual features had myriad characteristics that cannot be identified in the caricature. The icon *is* what Churchill in large part *is not*, and vice versa.

But this still is not enough. Sentences 1 and 2 fail to account for the Churchill image in and of itself. The two sentences need each other, for sure. Without each other's *otherness*, its Secondness, the icon as merely what it is, its Firstness, cannot become anything at all as a sign in the mind. We need both what it *is* and what it *is not*, as in sentence 3. So we have the equivalent of 'The icon *both* is (+) what it is *and* what it is not (−),' or '$+1 + -1 = 0$.' In the diagram adjacent to sentence 3, we have the central point, or vortex. But there are (as yet) no interrelations; there is only the interdependence of all possibilities of iconicity. You might possibly have called the squiggles in the sand 'Bob Hope,' 'Bill Clinton,' Charles Dickens's 'Scrooge', or one of many other people. But you did not. You identified the pattern as 'Churchill.' The central point, containing the range of all *possibilities*, cannot help but hold *contradictory* and even *inconsistent* images in its *both-and* embrace. But when you initially made your claim that it is 'Churchill,' you could have done so with no doubts in mind. At that juncture, it was *either* 'Churchill,' *or* nothing at all.

And yet…we still have not gone far enough. Sentences 1, 2, and 3 tell us about *possibilities* for iconicity: what a particular icon *is*, and what it *is not*, after we have interpreted it *as* a sign. But what about error, a change of mind, rejection of one interpretation in favor of another one? In response to this question, what if we turn sentence 3 inside out. We would have something tantamount to sentence 4, which is comparable to 'The icon is *neither* (−) what it is *nor* (−) what it is not, or $-1 + -(-1) = 0$.' Now we certainly wish to rebel, and with a vengeance: sentence 3 or sentence 4, what is the difference? Either way, we are left with zero, zilch. It is either blackness, a total blank, nothing at all, or it is whiteness, still an empty nothing. However, think about blackness as the absorption of the entire visible spectrum of wavelengths: all colors contained within and nothing given in return. And think about whiteness as the reflection of that same spectrum: all colors given and nothing retained within. In this sense, blackness and whiteness complement one another, like Yin and Yang. We cannot have the one without the other. *Both-and* and *neither-nor* must have a right to their place within semiosis just as much as *either/or*.

Now, put all this another way: notice that in the four sentences in Figure 2 we have the assertion of something, its negation, both its assertion and its negation, and neither its assertion nor its negation. Assertion is '$+1 \times +1 = +1$,' or '1^2.' Negation is '$-1 \times -1 = 1$,' or '-1^2.' Now the problem is with the square root of '−1' ($\sqrt{-1}$). It simply has no clear-cut answer. Apparently it neither *is* (+1) nor is it *not* (−1), or it can be conceived as both what it *is* (+1) and what it *is not* (−1). Take your pick as you so desire. Regarding this conundrum, mathematicians finally ended up by assigning the symbol '*i*' to '$\sqrt{-1}$.' But what is this '*i*,' this 'imaginary' value that forces itself on us when we wish to give account of the nature of a sign in the mind? Mathematicians called the square roots of negative numbers 'imaginary,' because such numbers were not compatible with the 'real' numbers – or, for that matter, with what we would like to consider 'reality.' Eventually, however, mathematicians came to realize that certain equations – most strikingly in relativity and quantum theory – could not be solved without the use of imaginary numbers, even though they continued to consider them strange and unwanted.

Contemplate, if you will, the sheer appearance of inordinate abstraction in the preceding paragraphs, and, I would suggest, you will find yourself gradually easing toward pure iconicity.

The Basic Nature of the Icon

An icon in the pure sense *is* what it *is*. When we sense it *as* an icon, Secondness has already entered the semiotic scene, for the icon now enjoys some *other* – ourselves as potential interpreting agents – and we as icons enjoy some *other* – the icon.

We might say that (1) the icon is in the *image of*, *similar to*, and *interdependent with* something other, (2) that something other is an index that *interacts with* what the icon *is not*, and (3) a potential Interpretant – consisting of the interpreting agent and the emergent sign meaning – of the icon brings the *is* and the *is not* together and mediates between them in such a manner that there is *both* the *is*, *and* the *is not*, and at the same time there is *neither* the *is*, *nor* the *is*

not. We see the icon as an icon, although deep down we know full well that it is not itself an icon in the pure sense but rather the sign that happened to be a possible icon, ready and willing to interact with us to become an index and an interpreted sign wrapped up in linguistic embossment: symbols. And so we talk interminably about this icon here and now, and any number of absent icons and actual icons, and the word 'icon' and other words having to do with 'icons.' But at its most basic, an icon emerges out of the central point, the vortex, pure 'emptiness,' of Figure 1. Then it enters into our anticipations and expectations and hopes and desires and fears. We initially experience the icon as 'some-*thing*' that is like 'some-*thing*' else that might bring on pleasantness or unpleasantness, depending on the context. But, at this moment, we are now far removed from mere 'emptiness.' It is like going from zero, '0,' to the 'empty set,' 'Ø.' Zero is just zero. It is emptied of everything, including even the memory of numbers. The empty set, in contrast, is just that: something that we notice happens to be empty. It is the 'noticed absence' of something that was or could have been or might possibly be partially or wholly filling the unoccupied space.

So we have 'pure emptiness' and the 'noticed absence' of something and the pluses and the minuses implied by Figure 2. Then comes the icon (or sign or Representamen) as Firstness, followed by an index (or semiotic Object) as Secondness, that is in need of a symbol (or Interpretant) to perform its role of mediation. All this, prior to the iconic sign's becoming an actual sign *for* us and construed *as* such-and-such (an index) because it carries a hefty load of characteristics that are of such-and-such a nature (a symbol). The initial stage of the Representamen, semiotic Object, and Interpretant is just that, the initial stage of a sign's process of becoming an icon, and only then can it take on actual indexical and symbolic properties. Which is to say once again that of the three sign types, the icon is all-important, for without it, indices and symbols could not have begun their becoming. Thus we see that in the final analysis, articulating iconicity is a hopeless task: once we sense it and say it, it is no longer *just* an icon, but is already something else.

Idealization

H van de Koot, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

All scientific disciplines make certain idealizations about the data they are concerned with, and linguistics is no exception. Particularly in theoretical linguistics, much progress has been made possible by the distinction between competence and performance, where competence represents two kinds of idealization over the data that linguists work with.

The first reflects common practice in other empirical sciences: competence ignores noise in the data. As Chomsky (1965: 3) put it: "Linguistic theory is concerned primarily with an ideal speaker-listener, in a completely homogeneous speech-community, who knows its language perfectly and is unaffected by such grammatically irrelevant conditions as memory limitations, distractions, shifts of attention and interest, and errors [...] in applying his knowledge of the language in actual performance." This kind of abstraction is comparable to that made by an astronomer who assumes, for the purposes of calculating interplanetary forces, that the earth is a perfectly round object, despite the fact that its many mountains and troughs do not qualify it as such.

The second idealization implied by the competence-performance distinction is an abstraction from considerations of language use (comprehension and production). Thus, competence is a theory of an ideal speaker-hearer's knowledge of language and may tell us very little about how that knowledge is put to use in actual linguistic performance. It is fair to say that this second idealization is less widely accepted than the first. Some believe it is unnecessary, while others believe that we do not really have a theory of human language at all if we do not understand the mental processes that underlie it. There are a number of responses to such objections, two of which are briefly discussed in this article.

To begin with, linguists simply would not know as much about human language as they do today had they felt compelled to base their theories solely on psycholinguistic experimentation or computational modeling. Although research in psycholinguistics and computational linguistics has certainly increased our understanding of human language processing, hypotheses in this domain typically have recourse to the theory of competence. For example, it is often assumed that the human parser, when confronted with more than one possible continuation of the parse, displays particular preferences. But the hypothesized preferences rely on assumptions about the structures the parser builds, which are themselves derived from competence theory. In short, we cannot easily develop theories about *how* a computational device computes something if we do not know *what* that device is computing.

Finally, competence theory seems to express an irreducible aspect of human language. Suppose two computers were built with radically different underlying hardware architectures that, moreover, matched up with radically different computational processes. Suppose furthermore that both machines passed a kind of Turing test for language: their performance is indistinguishable from that of native speakers of some natural language. In this situation one would want to say that both computers speak that language, but the notion of identity required for this cannot be captured at the level of hardware or computation. Apparently, the commonsense notion of natural language is based on regularities in the mapping between sound and meaning. But the function that specifies these regularities is the competence grammar.

Ideational Theories of Meaning

E J Lowe, University of Durham, Durham, UK

© 2006 Elsevier Ltd. All rights reserved.

Ideational theories of meaning are commonly attributed to 17th- and 18th-century empiricist philosophers such as Thomas Hobbes, John Locke, George Berkeley, and David Hume, and received severe criticism from 20th-century philosophers of language, notably Gottlob Frege and Ludwig Wittgenstein. Unfortunately, the work of the earlier philosophers was seriously misunderstood by their later critics, and much of the criticism was misdirected. In fact, it is highly debatable whether the empiricist philosophers in question were offering theories of *meaning* in anything like the sense that the phrase 'theory of meaning' would now be understood (see Hacking, 1975, chapter 5).

Locke devoted an entire book (Book III, 'Of Words') of his greatest work, *An Essay Concerning Human Understanding* (Locke, 1975) to the topic of language, focusing on the communicative function of language, the advantages of language, and the abuses of language. According to Locke, the main purpose of language is to serve as a medium for the communication of thought from one thinker to another. Locke, like many of his contemporaries, favored an ideational view of thought – that is, he believed that thinking is essentially an exercise of the faculty of imagination and that thoughts consist in sequences of *ideas* in the minds of thinkers. *Idea* was a term of art in early modern philosophy, as ubiquitous then as the term *concept* is in present-day philosophical writing and playing a partly similar role, to denote a component or ingredient of the contents of thoughts. However, the empiricist philosophers used it equally to denote a component or ingredient of the contents of *sensory experiences*, reflecting the tight connection they presumed to obtain between thought and perception. Locke famously claimed that words "in their primary or immediate signification stand for nothing but the ideas in the mind of him that uses them" (Locke, 1975: 405) – one of the most misunderstood claims in the history of philosophy. Modern readers of Locke are apt to interpret him as claiming that the *meaning* of a word is an idea in the mind of the speaker, which suggests that he adopted a thoroughly subjectivist – indeed, almost solipsistic – theory of meaning. But such an interpretation mistakenly conflates *signification*, as Locke uses this term, with *meaning* in the semantic sense. Locke is not claiming that words *refer to* or *denote* ideas in the mind of the speaker, but simply that speakers primarily use words to *express* the contents of their own thoughts, for the purpose of communicating those thoughts to others. Locke could happily concede that 'dog' in my mouth refers to *dogs*, not to my *idea* of a dog. His point is merely that when I assert, for example, 'Dogs bark,' I am expressing a thought that I have concerning dogs – a thought which is about dogs by virtue of containing as one of its ingredients my *idea* of a dog.

To clarify this matter, it is useful to distinguish between three quite different kinds of relations: *semantic* relations, *cognitive* relations, and *expressive* relations (see Lowe, 1995: 145 and Figure 1).

Semantic relations are *word-to-world* relations, such as the reference relation between the word 'dog' and dogs. Cognitive relations are *thought-to-world* relations, such as the intentional relation between my idea of a dog and dogs, by virtue of which the former is 'about' the latter, or has the latter as its 'intentional object.' Expressive relations are *word-to-thought* relations, such as the signification relation (in Locke's sense) between the word 'dog' as used by

Figure 1 Locke's dog-legged semantic theory.

me and my idea of a dog. In these terms, modern critics of Locke and like-minded early-modern empiricist philosophers may be accused of misconstruing their account of linguistic signification as a theory of semantic relations, when in fact it is a theory of expressive relations. Locke's primary interest lies not in semantics but in the nature of thought and its relation to language, that is, in cognition and expression. Of course, given an account of word-to-thought (expressive) relations and an account of thought-to-world (cognitive) relations, it is possible to construct an account of word-to-world (semantic) relations, although it seems that Locke himself was not much interested in doing this in any detail. Such an account of word-to-world relations will be, in Simon Blackburn's vivid phrase, a 'dog-legged' semantic theory (Blackburn, 1984: 40), because it takes such relations to be the product of two other kinds of relations, cognitive and expressive. There may be problems with semantic theories of this type, but they will only be obscured by misunderstanding the Lockean theory of linguistic signification as *itself* being a theory of semantic, as opposed to expressive, relations. In saying that words are *signs* of ideas in the minds of speakers, Locke means that they are *indicators* of those ideas, which speakers can exploit to enable an audience to gain knowledge of what they are thinking (see Ott, 2004). Locke presumes that signification of this kind is artificial – the product of human invention – rather than natural, but that it is otherwise comparable to the indicator relation between dark clouds and impending rain, the former constituting evidence for the latter.

To evaluate the Lockean approach to language, we need to probe a little more deeply into his account of thought and ideas. Locke divides ideas into *simple* ideas of sensation and reflection, and *complex* ideas that are compounded by the mind out of those simple ideas. By 'reflection' Locke means what would now be called 'introspection.' Examples of simple ideas of sensation would be our ideas of colors, taste, and sounds, while examples of simple ideas of reflection would be our ideas of basic mental activities, such as thinking, desiring, and willing. According to Locke, many of our complex ideas are acquired by the mental process of *abstraction*, or what we might now call 'selective attention,' when we notice that certain types of simple ideas regularly accompany each other in our experience. For example, our complex idea of an *apple* will include various simple ideas of shape, size, color, and taste which we find that we regularly experience in conjunction with one another. It is a matter for dispute among Locke scholars whether or not he conceived of sensory ideas as mental *images*, and the textual evidence is far from conclusive (see Lowe, 1995: 35–47). It is much clearer that Berkeley, writing a little later, held an imagistic view of ideas and, perhaps wrongly, construed Locke as holding one too. Berkeley famously criticized Locke's theory of abstraction as being incoherent, but the cogency of the criticism seems to depend upon the interpretation of Locke's view of ideas as being imagistic. (Berkeley urged that Lockean abstract ideas must lack determinacy of content in a way that seems problematic only on the assumption that such ideas are, or are relevantly like, images: see Lowe, 1995: 158–161.) Setting aside the controversy over whether or not Locke was an imagist, the essential features of his ideational conception of thought reduce to the following. First, Locke is clearly committed to a strong version of the doctrine that thought is independent of language. Indeed, his central aim in discussing language is to show how easily language can lead us astray if we fail to notice the differences between it and thought. Second, he clearly believes that thinking, involving as he takes it an exercise of the faculty of imagination, is intimately related to and, with respect to its content, ultimately wholly indebted to *perceptual experience*, both sensory and introspective.

Modern critics of ideationism are not only apt to misconstrue the ideational account of linguistic signification as being a semantic, as opposed to an expressive, theory, but also to oversimplify the object of their criticism. For instance, it is sometimes lampooned as maintaining that *every* word in a speaker's mouth signifies a discrete idea in the speaker's mind, including words such as 'not' and 'but,' which Locke himself classifies as 'particles' and to which he devotes a chapter in the *Essay*. It is easy enough to poke fun at the suggestion that 'not' signifies an idea of 'notness,' in the way that 'red' supposedly signifies an idea of redness. But Locke himself suggested nothing so preposterous, contending instead that negative particles are used to convey a speaker's mental act or attitude of *denial* with respect to a certain thought-content (Locke, 1975: 471). Berkeley's version of ideationism was still more sophisticated, recognizing many uses of language other than simply to express the speaker's ideas – for example, to invoke an emotive response in an audience – and allowed, too, that often we think 'in words' rather than exclusively 'in ideas' (see Olscamp, 1970: 130–153).

Undoubtedly, the disfavor into which ideationism fell during the 20th century was largely due to the conviction that it rendered linguistic meaning excessively subjective. Frege's attack on it was integral to his more general onslaught on psychologism, which he saw as a dire threat to the objectivity of logic and mathematics. This is why he is at pains to distinguish sharply between 'ideas,' which he regards as purely

subjective psychological entities, and 'senses' of expressions, which he regards as mind-independent and intersubjectively graspable abstract objects (see Frege, 1960). Wittgenstein is equally antagonistic toward ideationism, which is a prime target of his famous 'private language argument' (see Wittgenstein, 1958: 94–96). Here again the complaint is that ideas are unsuited by their irredeemably subjective and private character to be recruited for a workable account of intersubjective linguistic meaning and communication, and that ideationism unavoidably degenerates into some form of scepticism or relativism.

To the extent that criticisms focusing on the privacy of ideas construe ideationism as postulating ideas as the *meanings* of words, they are misplaced for the reasons explained above. Even so, it is fair to ask of the ideationist how words can serve to *communicate* ideas, given the privacy of the latter – a privacy that Locke himself acknowledged and emphasized. Indeed, for Locke, it is precisely *because* ideas are private – 'invisible, and hidden from others' – that language, in the form of 'external sensible signs,' is needed to 'lay them before the view of others' (Locke, 1975: 405). One might suppose it to be a fatal difficulty for ideationism that no one has direct access to the ideas of another speaker and so is never in a position to tell whether or not the idea that he or she associates with a given word resembles the idea that is associated with it in the mind of someone else. However, Locke himself was fully cognizant of this seeming difficulty and was not at all disconcerted by it. It was he, indeed, who first drew attention to the notorious puzzle now known as the 'inverted spectrum' problem – the question of how I can tell whether the way in which blue things look to me might not be how yellow things look to someone else, and vice versa (see Locke, 1975: 389). Locke's answer is that it simply doesn't matter, for the purpose of the successful communication of thoughts between people concerning blue or yellow things. However, one might agree with Locke about this while failing to see how he was in a position to say it himself, given his commitment to an ideational theory of linguistic signification. For one might suppose that such a theory takes success in communication to consist in the *replication* in the hearer's mind of ideas which the speaker associates with the words that he or she utters. But there is no reason to tie ideationism to such a doctrine, nor any evidence that ideationists such as Locke espoused it. Ideationism is at most committed to the thesis that in successful communication of the speaker's thoughts to a hearer, ideas are evoked in the hearer's mind which *correspond* to those in the speaker's mind, in a sense of 'correspondence' which does not imply resemblance or replication. That such a correspondence obtains is subject to intersubjective confirmation without imposing upon the persons concerned the impossible burden of comparing each other's ideas, and it may be taken to be set up through the social processes of language teaching and learning (see Lowe, 1996: 172–177).

Identity and Language

J E Joseph, University of Edinburgh, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

This article considers what identities are, how they depend on language, how that dependency may have come about, and how linguistics and affiliated disciplines have gone about analyzing it. Secondly, it examines how the very way in which we identify and conceive of languages is bound up with identity, usually that of a nation.

What Is Identity?

Your identity is, very simply, who you are. It has two basic aspects: your name, which serves first of all to single you out from others (the deictic function), and then that deeper, intangible something that constitutes who you *really* are, which we might think of as the *meaning* of your name (the semantic function). Names are obviously pieces of language, but less obvious is the role played by the language you speak, and how you speak it, in constructing that other, deeper aspect of your identity, both for yourself and others.

Imagine a group of strangers at a bus stop. The bus they are waiting for drives past without stopping, and the following remarks ensue:

A: Well fuck me.
B: I say, wasn't that the 23?
C: I'm like not believing this.

Picture in your mind what A, B, and C look like. You can probably say something about how they are dressed, their background, what they do, what they are like, and whether you would like them or not. It is extraordinary how much we are able to infer from what are, after all, a few squiggles on a page. We have an instinctive capacity to construct the identity of a whole person in our minds based on minimal input, and it is most effective when the squiggles represent something the person said.

Self-identity has long been given a privileged role in identity research. But the identities we construct for ourselves and others are not different in kind, only in the status we accord them. The gap between the identity of an individual and of a group – a nation or town, race or ethnicity, gender or sexual orientation, religion or sect, school or club, company or profession, or the most nebulous of all, a social class – is most like a true difference of kind. Group identities seem more abstract than individual ones, in the sense that 'Brazilianness' doesn't exist separately from the Brazilians who possess it, except as an abstract concept. Yet combinations of such abstractions are what our individual identities are made of, and group identity frequently finds its most concrete manifestation in a single, symbolic individual. The group identities we partake in nurture our individual sense of who we are, but can also smother it.

Bourdieu, discussing regional and ethnic identities, made an important point that applies to many other types of identity as well: although they essentialize what are actually arbitrary divisions among peoples, and in this sense are not 'real,' the fact that, once established, they exist as mental representations makes them every bit as real as if they were grounded in anything 'natural.'

> One can understand the particular form of struggle over classifications that is constituted by the struggle over the definition of 'regional' or 'ethnic' identity only if one transcends the opposition [...] between representation and reality, and only if one includes in reality the representation of reality, or, more precisely, the struggle over representations [...].
>
> Struggles over ethnic or regional identity – in other words, over the properties (stigmata or emblems) linked with the *origin* through the *place* of origin and its associated durable marks, such as accent – are a particular case of the different struggles over classifications, struggles over the monopoly of the power to make people see and believe, to get them to know and recognize, to impose the legitimate definition of the divisions of the social world and, thereby, to *make and unmake groups* (Bourdieu, 1991: 221).

The role played by names, labels, and other linguistic forms of classification-*cum*-text in the making and unmaking of groups along the lines Bourdieu described is why identity is ultimately inseparable from language.

Identity and the Functions of Language

Dunbar (1996) located the origin of language in the needs of higher primates to form social alliances in order to deal with challenges in their environment, including threats from powerful members of their own species. He believes that the essential functions of language for evolutionary purposes were phatic ones, with gossip – language of purely social content exchanged for social purposes – being the equivalent of the grooming that primates use to form and maintain social bonds. The move from physical to linguistic grooming is attributed by Dunbar to increasing group size. Early humans "must have faced a terrible dilemma: on the one hand there was the relentless ecological pressure to increase group size, while on

the other time-budgeting placed a severe upper limit on the size of groups they could maintain" (Dunbar, 1996: 77). Language made it possible to increase group size without losing social cohesion or the time needed to gather and hunt food. Because language can be directed at several people simultaneously, the rate of grooming is increased manifold.

Dunbar notes, "Being able to assess the reliability of a prospective ally becomes all-important in the eternal battle of wits" (Dunbar, 1996: 78–79). On the one hand, language serves the purposes of the individual who is seeking to make an alliance: "It allows you to say a great about yourself, your likes and dislikes, the kind of person you are; it also allows you to convey in numerous subtle ways something about your reliability as an ally or friend" (Dunbar, 1996: 78). It also serves the person being courted as a prospective ally: "Subtle clues provided by what you say about yourself – perhaps even how you say it – may be very important in enabling individuals to assess your desirability as a friend. We get to know the sort of people who say certain kinds of things, recognizing them as the sort of people we warm to – or run a mile from" (Dunbar, 1996: 79). He concludes, "Language thus seems ideally suited in various ways to being a cheap and ultra-efficient form of grooming. [. . .L]anguage evolved to allow us to gossip" (Dunbar, 1996: 79).

If we think about language from this perspective, its primary purpose is no longer necessarily restricted to one of the two traditionally ascribed to it, communication (by a speaker having an intention and wishing to transmit it to listeners) and representation (of the universe, as analyzed into the logical categories that languages are thought to contain). Before either of these, and in many regards enveloping them both, language exists, in this reversed perspective, for the purpose of *reading the speaker*.

Sociolinguistic inquiry into identity and language is concerned with how people read each other, in two senses. First, how the meanings of utterances are interpreted, not just following idealized word senses and rules of syntax as recorded in dictionaries and grammars, but in the context of who is addressing whom in what situation. Secondly, how speakers themselves are read, in the sense of the social and personal identities their listeners construct for them based on what they say and how they say it (a complex process, because most speakers' output is already shaped in part by how they have read their listeners). Every day each of us repeatedly undertakes this process of constructing our reading of people we encounter, in person, on the telephone, on the radio or the screen, or in writing, including on the Internet, based on their language – what they say and how they say it.

Targeting Identity in the Analysis of Language

Modern linguistics has moved slowly but steadily toward embracing the identity function as central to language. The impediment has been the dominance of the traditional outlook, which takes representation alone to be essential, with even communication relegated to a secondary place. This outlook was never the only one available, however, and when early 20th-century linguists such as Jespersen and Sapir came to investigate how language functions to define and regulate the role of the individual within the social unit at the same time that it helps to constitute that unit, they were not without predecessors. It was just that mainstream linguistics as it had developed within the 19th century was not inclined to see such questions as falling within its purview.

An overview of the development of such inquiry within linguistics and adjacent fields can be found in Joseph (2004), from which some key moments will be excerpted here. The first is Labov (1963), a study of the English dialect of Martha's Vineyard, an island off the coast of Massachusetts, where the diphthongs in words such as *right* and *house* are pronounced as [əy] and [əw] rather than [ay] and [aw]. This feature is not found in the dialects of the mainlanders who 'summer' on Martha's Vineyard, and with whom the Vineyarders (year-round residents) have a complex relationship of dependency and resentment. "It is apparent that the immediate meaning of this phonetic feature is 'Vineyarder.' When a man says [rəyt] or [həws], he is unconsciously establishing the fact that he belongs to the island: that he is one of the natives to whom the island really belongs" (Labov, 1963: 307). This is very much the sort of analysis of the effect of linguistic identity on language form that would characterize work in the 1990s and since, though it was sidelined in the mid-1960s by the statistical charting of variation and change.

In the meantime, one particular identity focus – gender – led the way in directing attention to the reading of identity in language. Lakoff (1973) argued that, in both structure and use, languages mark an inferior social role for women and bind them to it. Gender politics is incorporated directly into the pronoun systems of English and many other languages, through the use of the masculine as the 'unmarked' gender (as in 'Everyone take his seat'). Lakoff points to features that occur more frequently in women's than in men's English, such as tag questions, hedges,

intensifiers, and pause markers, which as marks of insecurity and of the role women are expected to occupy are fundamental to maintaining the status quo in gender politics.

As the notion of separate men's and women's language was accepted, the more general notion of the language–identity link was let in through the back door, leaving the way open for the study of group identities of all sorts beyond those national and ethnic ones traditionally associated with language difference. This was a challenge to a sociolinguistics that had been fixated on class differences. By the mid-1980s this shift was underway in the work of, for example, Gumperz (1982), Edwards (1985), and Le Page and Tabouret-Keller (1985), though it was really in the 1990s that it would come to occupy the mainstream of work in sociolinguistics and linguistic anthropology. (For a small but representational sample of studies see, on the sociological end, Fishman (1999); on the anthropological, Schieffelin *et al.* (1998); and in discourse analysis, Wodak *et al.* (1999).)

This work also received significant input from social psychology, where one approach in particular needs to be singled out: Social Identity Theory, developed in the early 1970s by Tajfel. In the years following his death in 1982, it came to be the single most influential model for analyzing linguistic identity. Tajfel (1978: 63) defined social identity as "that part of an individual's self-concept which derives from his knowledge of his membership of a social group (or groups) together with the value and emotional significance attached to that membership." Within this simple definition are embedded at least five positions that in their time were quite revolutionary: that social identity pertains to an individual rather than to a social group; that it is a matter of *self-concept*, rather than of social categories into which one simply falls; that the fact of *membership* is the essential thing, rather than anything having to do with the nature of the group itself; that an individual's own knowledge of the membership, and the particular value they attach to it – completely 'subjective' factors – are what count; and that emotional significance is not some trivial side effect of the identity belonging but an integral part of it.

Beyond this, Social Identity Theory marked a break with other approaches in the fact that it was not concerned with analyses grounded in a notion of 'power,' but simply in the relative hierarchizations that people seem instinctively to impose on ourselves, most particularly in our status as members of 'in-groups' and 'out-groups,' which would come into even greater prominence in the 'Self-Categorization Theory' that developed as an extension of the original model, notably in the work of Tajfel's collaborator Turner (see Tajfel and Turner, 1979; Turner *et al.*, 1987; Turner, 1991).

Partly under the influence of such work, sociolinguists were beginning to reorient their own object of investigation. Milroy (1980) reported data from studies she conducted in Belfast showing that the 'social class' of an individual did not appear to be the key variable allowing one to make predictions about which forms of particular linguistic variables the person would use. Rather, the key variable was the nature of the person's 'social network,' a concept borrowed from sociology that Milroy defined as "the informal social relationships contracted by an individual" (Milroy, 1980: 174). Where close-knit localized network structures existed, there was a strong tendency to maintain nonstandard vernacular forms of speech – a tendency difficult to explain in a model such as Labov's, based on a scale of 'class' belonging where following norms of standard usage marked one as higher on the hierarchy and entitled to benefits that most people desire. Labov's early work on Martha's Vineyard had suggested that the answer lay in identity, specifically in the value of belonging to a group who, although not highly placed in socioeconomic terms, could nevertheless claim something valuable for themselves (in the Martha's Vineyard case, authenticity). Milroy's book provided statistical backing for such an explanation.

Although the inner workings of the social network depend somewhat on the amount of personal contact, the essential thing is that its members share *norms*. As attention turned to understanding the nature of these norms, two much publicized views had an impact. Fish (1980) had devised the concept of the 'interpretative community' to account for the norms of reading whereby people evaluate different readings of the same text as either valid or absurd. An interpretative community is a group sharing such a set of norms; its members may never come into direct physical contact with one another, yet share norms spread by the educational system, books, or the media. Soon after, Anderson (1991, first published in 1983) proposed a new understanding of the 'nation' as an 'imagined community,' whose members, like that of the interpretative community, will never all meet one another let alone have the sort of regular intercourse that creates a 'network.' What binds them together is the shared belief in the membership in the community.

Notably with the work of Eckert, sociolinguistic investigation of groups ideologically bound to one another shifted from statistically based examination of social networks to more interpretative examination of 'communities of practice,' defined as "an aggregate of people who come together around mutual

engagement in an endeavor" (Eckert and McConnell-Ginet, 1992: 464). In the course of this endeavor there emerge shared beliefs, norms, and ideologies, including, though not limited to, linguistic and communicative behavior. The advantage of the community-of-practice concept is its openness – any aggregate of people can be held to constitute one, so long as the analyst can point convincingly to behavior that implies shared norms or, better still, elicit expression of the underlying ideologies from members of the community. This line of research is thus continuous with another one that has focused more directly on the normative beliefs or ideologies by which national and other group identities are maintained. Some early work along these lines was published in Wodak (1989) and Joseph and Taylor (1990), and subsequently a great deal more has appeared, e.g., in Verschueren (1999), Blommaert (1999), and Kroskrity (2000).

Other features of recent work on language and identity include the view that identity is something constructed rather than essential and performed rather than possessed – features that the term *identity* itself tends to mask, suggesting as it does something singular, objective, and reified. Each of us performs a repertoire of identities that are constantly shifting, and that we negotiate and renegotiate according to the circumstances.

Coconstructing National Identity and Language

As mentioned at the outset, it is not simply the case that identity is built upon language. The reverse is also true. One of the first obstacles to be overcome in establishing a national identity is the nonexistence of a national language. The 'nation–state myth' – that basic view of the world as consisting naturally of nation–states – is bound up with an assumption that national languages are a primordial reality. Whatever difficulty we might have in determining the borderlines of who 'the Germans' are, whether the German-born children of Turkish immigrants are German for instance, or whether certain Alsatians are French or German, the German language is going to figure significantly in the equation. Hitler attempted to justify his initial invasions of neighboring countries on the grounds that these German-speaking peoples were inherently part of the German nation; and, as Hutton (1999) has shown, his policies of oppression and ultimately extermination of the Jews were underpinned by the argument that, although their language, Yiddish, was a form of German, their lack of a nation gave them the perverse racial peculiarity of not being able to have a 'mother tongue.' They therefore did not belong to the German body politic but were seen as a parasite within it.

But whether Bohemian, Alsatian, and Yiddish dialects were part of 'the German language' were not facts given in advance, nor even ones that a linguist could establish scientifically. The 'German language,' like every national language, is a cultural construct. It dates from the 16th century and is generally credited to Luther, who, in translating the Bible, strove to create a form of German that might unite the many dialect groups across what until the late 19th century was a patchwork of small and large states, linguistically very diverse. (This story is itself a part of the cultural construct, and although not false, it is considerably oversimplified – in order to shape up as a proper 'hero' myth, it ignores or marginalizes the work of many other individuals and broader cultural changes.) The prototype of the modern national language was Italian, which may seem surprising, given that Italy did not become a political nation until 1860, with full unification coming in 1870, just a year before that of Germany. Or perhaps not so surprising – the political divisions of the Italian peninsula may have been precisely what motivated the creation of cultural unity through linguistic means.

In the Romance-speaking world during the thousand years from the fall of the Roman Empire to the Renaissance, 'language' meant Latin, used for all official and written purposes, though what people spoke in nonofficial contexts was a local dialect, historically related to Latin though significantly different from village to village. There was, then, no 'Italian language.' That concept and its realization are credited – heroically, and again only semimythically – to Dante, author of the *Divina Commedia*. Dante's treatise *De vulgari eloquentia* (c. 1306), not published until 1529, lays out the process by which he claimed to discover, not invent, the national language of a nation that would take five and a half centuries to emerge politically. To the modern reader this all seems a fiction, a pretense of discovery in what will actually be Dante's invention of an illustrious vernacular – which will in turn camouflage how much of it is actually based on his native Tuscan. But Dante's *volgare illustre* became the template on which other modern European standard languages were modeled.

Once the national languages existed, however, their invention was promptly forgotten. The people for whom they represented national unity inevitably came to imagine that the language had always been there, and that such dialectal difference that existed within it was the product of recent fragmentation, when in fact it had preceded the unification by which the national language was forged. In the words of one prominent historian:

> National languages [. . .] are the opposite of what nationalist mythology supposes them to be, namely the primordial foundations of national culture and the matrices of the national mind. They are usually attempts to devise a standardized idiom out of a multiplicity of actually spoken idioms, which are downgraded to dialects [. . .]. (Hobsbawm, 1990: 51)

By the early 19th century this 'nationalist mythology' would lead to strong Romantic theorizations of national political identity being grounded in a primordial sharing of language. One of the strongest expressions was that of Fichte:

> The first, original, and truly natural boundaries of states are beyond doubt their internal boundaries. Those who speak the same language are joined to each other by a multitude of invisible bonds by nature herself, long before any human art begins; they understand each other and have the power of continuing to make themselves understood more and more clearly; they belong together and are by nature one and an inseparable whole. (Fichte, 1968 [1808]: 190–191)

Fichte was writing to rouse the 'German nation' to repel the advance of Napoleon. He was successful in doing so. However, in 1870 the shoe was on the other foot, when the Franco-Prussian War led to the German annexation of Alsace, a German-speaking province that had been part of France for more than two centuries and whose population was mainly loyal to France, despite their linguistic difference. This provoked a sharp turn away from the Fichtean view on the part of French linguists such as Renan (1882), who formulated a new view of national identity as based not on any primordially determining characteristic such as language, but on a shared will to be part of the same nation, together with shared memories.

The nation, in other words, exists in the *minds* of the people who make it up. This is the conception that Anderson (1991: 6) would return to in defining the nation as "an imagined political community." The 'legacy of memories' Renan pointed to would dominate future philosophical and academic attempts to analyze national identity. The other element, the collective 'will' of the people, would, however, have the deepest political impact, starting with the redrawing of the map of Europe at Versailles in 1919. It has continued to be the assumed basis for the legitimacy of the political nation up to the present time.

Billig, a colleague and collaborator of Tajfel, has explored how the "continual acts of imagination" on which the nation depends for its existence are reproduced (Billig, 1995: 70), sometimes through purposeful deployment of national symbols, but mostly through daily habits of which we are dimly aware at best. Examples include the national flag hanging in front of the post office and the national symbols on the coins and banknotes we use each day. Billig introduced the term *banal nationalism* to cover the ideological habits that enable the established nations of the West to be reproduced. In Billig's view "an identity is to be found in the embodied habits of social life" (Billig, 1995: 8), including language. Smith (e.g., 1998, Chapter 8) has emphasized how much of the effort of nationalism construction is aimed at reaching back to the past in the interest of 'ethno-symbolism,' and this can be seen particularly in the strong investment made by modern cultures in maintaining the 'standard language,' by which is meant a form resistant to change, hence harking backward. Hobsbawm placed great stress on the fact that enthusiasm for linguistic nationalism has historically been a phenomenon of the *lower middle class*.

> The classes which stood or fell by the official use of the written vernacular were the socially modest but educated middle strata, which included those who acquired lower middle-class status precisely by virtue of occupying non-manual jobs that required schooling. (Hobsbawm, 1998: 117)

These are also the people who become the mainstay of nationalism – not just by active flag-waving on symbolic occasions, but daily in the banal ways pointed to by Billig, including their use of 'proper language' and their insistence on its norms, for instance in conversation with their own children. Hobsbawm has suggested that, in Victorian times, the pattern was established whereby the lower middle classes (artisans, shopkeepers, and clerks) enacted their national belonging by showing themselves to be "the most 'respectable' sons and daughters of the fatherland" (Billig, 1998: 122). In other words, although their real identity was that of a social class, they masked it for themselves and others in a nationalistic guise. The mask was double-sided: in their obsession with 'speaking properly' as a mark of respectability, they were contributing to the linguistic construction of their nation.

At the start of this article, I wrote that identities are, first and foremost, names, and that the work of identity construction consists of supplying meaning for the name. In the case of national identity, language has traditionally been a key ingredient in this process for at least five reasons:

1. Groups of people who occupy contiguous territory and see themselves as having common interests tend to develop, over long stretches of time, ways of speaking that are distinctive to them, marking them out from groups who either are not geographically adjacent to them or else are perceived

as having different, probably rival, interests. In other words, language does tend to mark out the social features on which national belonging will come to be based – but it is only a tendency, because it also happens very frequently that the same way of speaking is shared by people with very different interests (religious ones, for instance), and that markedly different ways of speaking exist among a group of people who nonetheless see themselves as part of the same nation.

2. The ideology of national unity has favored a view that nations are real because those within them share a deep cultural unity, and this has coexisted with a widespread – indeed, nearly universal – belief that deep cultural unity is the product of a shared language. This is what Fichte meant by the 'invisible bonds' by which nature has joined those who speak the same language. Again, as with (1), it cannot be more than a tendency, because it is not the case that people who identify themselves as belonging to the same culture or nation think identically. Yet language is central to the *habitus* (an ancient term revived by Bourdieu): the fact that we spend our formative years attending long and hard to the task of learning words and their meanings from those around us results in our acquiring tastes, habits, and ways of thinking from them that will endure into adult life. The language does not somehow transmit culture and identity to its speakers – rather, the language is the *text* through the constant interaction with which older speakers transmit culture and identities (local and personal as well as national, ethnic, and religious) to the young. (In many cases the young will want an identity of their own and will attain it first of all by resisting the imposition of culture upon them by their elders.)
3. In addition to being the text of cultural transmission, the language is the principal medium in which texts of national identity in the more usual sense will be constructed. It is not the only such medium, nor the only powerful one, as Billig's exposition of 'banal nationalism' has shown. But the particular concepts that constitute a national identity correspond to words in the national language, embodied in 'sacred texts' of the nation such as a constitution or key works of the national literature, including the national anthem.
4. As universal education is adopted throughout the nation, inculcating standards of 'correct' language assumes a central role. Overtly, this is from a perceived duty to maintain the culture. However, as Hobsbawm has shown, such is the force of the language-culture-nation-class nexus that, especially for the upwardly mobile members of the lower middle class, being a 'proper' citizen and member of the community is inseparable from using 'proper' language.
5. Insofar as nations are not the historical essences they purport to be, but are constructs that inevitably involve a certain amount of arbitrary and even capricious divisions and classifications, when a nation wants to control who can live in it, vote in it, and enjoy state benefits, language can appear to be the most obvious test for deciding whether particular individuals belong to the nation or not. Most nations no longer have laws based on racial classification – which are rarely easy to apply in any case – yet many do require cultural qualifications to be met, which are likely to include language either overtly or indirectly.

Each of these factors has reinforced the others in giving the national language the force of a cultural–historical 'ethno-symbolic' myth as suggested by Smith (see earlier discussion). Within each, too, there is a contradiction or a caveat that has periodically pendulum-swung to prominence, such that the loss of belief in the national language and all it stands for is always potentially there and is bound to come to the fore at least periodically. The question that is unanswerable for now is whether national languages, together with the nations to which they are attached, represent a historical phase that is now on a course of decline heading for eventual disappearance, to be replaced with 'glocalization' – a term that has been coined to denote the combination of globalization with the resurgence of local, subnational sites of belonging – or whether they are an invention that has proven too useful for human social organization to be given up.

Introduction

'Identity' and 'sameness' mean the same; their meanings are identical. However, they have more than one meaning. A distinction is customarily drawn between **qualitative** and **numerical** identity and sameness. Things with qualitative identity share properties; so things can be more or less qualitatively identical. Poodles and Great Danes are qualitatively identical because they share the property of being a dog, but two poodles will (very likely) have greater qualitative identity. Numerical identity, however, is not a matter of more or less. Numerical identity requires absolute qualitative identity and can hold only between a thing and itself. Its name implies the controversial view that it is the only identity relation in accordance with which we can properly count (or number) things or at least that so counting has a special status: x and y are to be counted as one just in case x is numerically identical with y.

Numerical identity is our topic. It is at the center of various philosophical puzzles but seems to many to be utterly unproblematic – for what could be less problematic than the notion just characterized: that of the relation that everything has to itself and to nothing else? A possible resolution of this apparent paradox (Lewis, 1986) is that there are indeed genuine puzzles stated in the language of numerical identity, but they

practice.' *Annual Review of Anthropology 21*, 461–490.

Introduction

'Identity' and 'sameness' mean the same; their meanings are identical. However, they have more than one meaning. A distinction is customarily drawn between **qualitative** and **numerical** identity and sameness. Things with qualitative identity share properties; so things can be more or less qualitatively identical. Poodles and Great Danes are qualitatively identical because they share the property of being a dog, but two poodles will (very likely) have greater qualitative identity. Numerical identity, however, is not a matter of more or less. Numerical identity requires absolute qualitative identity and can hold only between a thing and itself. Its name implies the controversial view that it is the only identity relation in accordance with which we can properly count (or number) things or at least that so counting has a special status: x and y are to be counted as one just in case x is numerically identical with y.

Numerical identity is our topic. It is at the center of various philosophical puzzles but seems to many to be utterly unproblematic – for what could be less problematic than the notion just characterized: that of the relation that everything has to itself and to nothing else? A possible resolution of this apparent paradox (Lewis, 1986) is that there are indeed genuine puzzles stated in the language of numerical identity, but they

are not genuinely puzzles about identity, as they can be restated not using it. Philosophical debates about identity of which this is not true are just confusions.

The Logic of Identity

Numerical identity can be characterized, as just done, as the relation everything has to itself and to nothing else. But this is circular, because 'nothing else' just means 'no numerically non-identical thing.' It can be defined, equally circularly, as the smallest equivalence relation (an equivalence relation being one that is reflexive, symmetric, and transitive). Other circular definitions are available. Usually it is explained as the equivalence relation satisfying Leibniz's Law, the principle of the indiscernibility of identicals, that if x is identical with y then everything true of x is true of y. Intuitively this is right, but only satisfactory if 'what is true of x' is understood to include 'being identical with x'; otherwise, it is too weak to serve uncontroversially as a unique characterization of identity. Circularity is thus not avoided. The converse of Leibniz's Law, the principle of the indiscernibility of identicals, that if everything true of x is true of y, x is identical with y, is correspondingly trivial if 'what is true of x' is so understood, but with 'what is true of x' restricted, e.g., to qualitative, non-relational properties, becomes philosophically controversial.

Leibniz's Law itself has been subject to controversy in the sense that the correct explanation of apparent counterexamples has been debated. It is informative to be told that Hesperus is Phosphorus, but not that Hesperus is Hesperus (Frege, 1969); Giorgione was so-called because of his size, Barbarelli was not (Quine, 1963). Are these not cases in which something is true of x (Hesperus, Giorgione) but not of the identical y? No. The cases only illustrate the need for distinguishing Leibniz's Law from the principle of substitutivity: if 'x' and 'y' are co-designators they are substitutable everywhere without change of truth-value. The cases are not counterexamples to Leibniz's Law, but how best to explain such failures of substitutivity is debatable.

Relative and Absolute Identity

The view that characterizes identity as the equivalence relation that everything has to itself and nothing else and that satisfies Leibniz's Law may be called the classical view. These formal properties ensure that within any theory expressible by means of a fixed stock of one- or many-place predicates, quantifiers and truth-functional connectives any two predicates that can be regarded as expressing identity will be extensionally equivalent. They do not, however, ensure that a two-place predicate does express identity within a particular theory, for it may simply be that the descriptive resources of the theory are insufficiently rich to distinguish items between which the equivalence relation it expresses holds (Geach, 1972). For example, 'has the same income as' will satisfy these conditions in a theory whose descriptive resources do not enable one to distinguish persons with the same income (by not containing, e.g., the predicates 'is male,' 'is female').

Following Geach, call a two-place predicate with these formal properties in some theory an 'I-predicate' relative to that theory. Relative to a richer theory the same predicate, identically interpreted, may not be an I-predicate. If so it will not, and did not even in the poorer theory, express identity.

Quine has suggested that when a predicate is an I-predicate in a theory only because the language is limited, its sentences always can be reinterpreted so that the I-predicate in the newly interpreted theory does express identity. Each sentence will retain its truth-conditions, but the references of its subsentential parts will be different. Thus, Quine suggests, in a language that cannot distinguish possessors of the same income the predicates may be reinterpreted so that the predicate that previously expressed **having the same income** expresses identity. Correspondingly, there will be a shift in the ontology of the theory (from people to income groups) (Quine, 1963).

This situation provides the basis for one philosophical controversy about identity, whether identity is relative. Geach maintains that as no criterion can begiven by which a predicate expressing an I-predicate may be determined to express, not merely indiscernibility relative to the language, but absolute indiscernibility, we should jettison the classical notion of identity (Geach, 1991). Others, following Quine, regard classical identity as an always-legitimate interpretation of an I-predicate and indispensable to our understanding of quantification (Quine, 1963; Dummett,1991; Hawthorne, 2003).

Another, related, question, is whether numerical identity deserves its name. The procedure we use in counting is as follows: assign '1' to an object x and to whatever bears R to it and to nothing else, assign '2' to an object y to which '1' has not been assigned, to whatever bears R to it and to nothing else.... The number arrived at will be the number of objects in the domain counting by R. If R is an equivalence relation this procedure will yield a unique result. If R is not numerical identity a larger count will be possible using numerical identity, but if R is numerical identity no larger count will be possible. Thus, things related by numerical identity have to

be counted as one, whereas things related by weaker equivalence relations can be, but need not be, counted as one. So if numerical identity, classically characterized, is ever an intelligible interpretation of an I-predicate, it deserves its name.

Criteria of Identity

Leibniz's Law characterizes identity but provides no means of recognizing it – we cannot ever determine that x is y by first of all checking that everything true of x is true of y. Thus, we apply **criteria** of identity, standards by which identity is to be judged. Different kinds of thing have different criteria of identity and criteria of identity themselves have different logical forms. One distinction is between one-level and two-level criteria of identity (Williamson, 1990) for objects. The criterion of identity for numbers is two-level. The number of Fs is the number of Gs if and only if a one-one correlation exists between the concept F and the concept G. Numbers are the objects for which the criterion is stated but the condition is given as a relation not on those objects but on concepts (Frege, 1950). By contrast, the criterion of identity for sets given by the Axiom of Extensionality (sets are the same if they have the same members) and Davidson's (1980) criterion of event identity (events are the same if they have the same causes and effects) are one-level, the condition is given as a relation on the very objects for which the criterion is stated. Not all criteria of identity can be two-level. But it does not follow that the only legitimate notion of a criterion of identity remaining is that of a one-level criterion. Another option (Dummett, 1981) is to deny that a criterion of identity must be regarded as a criterion of identity for a type of **object**. At a basic level, on this view, what a criterion of identity is a criterion for, is the truth of a statement in which **no** reference to objects occurs. Such a statement may be expressed using demonstratives, for instance, by saying, 'This is the same cat as that,' pointing first to a tail and then a head. In this the demonstratives need not be construed as referring to objects anymore than reference is made to objects in a feature placing sentence such as, 'It's cold here' or 'It's colder here than there.'

Identity over Time

Criteria of identity can be employed synchronically, as in the example just given, or diachronically, to determine identity over time. Identity over time is a controversial notion, however, because time involves change. Heraclitus argued that one could not bathe in the same river twice because new waters were ever flowing in. Hume argued that identity over time was a fiction we substitute for a collection of related objects. Such views can be seen as based on a misinterpretation of Leibniz's Law: if a thing changes something is true of it at the later time that is not true of it at the earlier, so it is not the same. The answer is that what is true of it at the later time is, say, 'being muddy at the later time,' which was always true of it; similarly, what is true of it at the earlier time, suitably expressed, remains true of it. But the question remains of how to characterize identity across time through change given that such identity exists. On one view, a persisting object is to be thought of as perduring, having different temporal parts at different times, on another it is to be thought as enduring, existing at different times in its entirety (Lewis, 1986). On the former view, temporary qualities like being muddy are genuinely qualities but are possessed by the temporal parts of the persisting object, not the object itself. On the latter view, they are relations in disguise, relations that the persisting object stands in to different times.

Contingent Identity

Another controversy about identity is whether it can obtain contingently. Of course, there are contingently true identity statements – 'Benjamin Franklin was the first Postmaster General of the United States' – but Kripke (1980) argued that when the expressions flanking the identity sign were rigid designators designating the same object across all possible world (unlike 'the first Postmaster General') the identity statement had to be necessarily true, if true at all. Relatedly, he argued that identity itself was a necessary relation.

But some examples suggest that this conclusion is too sweeping – that even identity statements containing rigid designators may be, in a sense, contingently true. Consider a statue, Goliath, and the clay, Lumpl, from which it is composed (Gibbard, 1975). Imagine that Lumpl and Goliath coincide in their spatio-temporal extent. It is tempting to conclude that they are identical. But they might not have been. Goliath might have been rolled into a ball and destroyed, Lumpl would have continued to exist. The two would have been distinct.

The debate over contingent identity is concerned with the proper analysis of such examples.

Vague Identity

Like the impossibility of contingent identity, the impossibility of vague identity appears to be a straightforward consequence of the classical concept of

identity (Evans, 1978). For if a is only vaguely identical with b, something is true of it – that it is only vaguely identical with b – that is not true of b, so by Leibniz's Law, it is not identical with b at all. Of course, there are vague statements of identity – 'Princeton is Princeton Borough' (Lewis, 1988; 'Princeton' is indeterminate in denotation in standard usage between the township and the borough) – but the conclusion appears to follow that such vagueness is only possible when one or both of the terms flanking the identity sign is an imprecise designator. Relatedly, it appears to follow that identity itself must be a determinate relation.

But some examples suggest that this conclusion is too sweeping – that even identity statements containing precise designators may be, in some sense, indeterminate. Consider Everest and some precisely defined hunk of rock, ice and snow, 'Rock,' of which it is indeterminate whether its boundaries coincide with those of Everest. It is tempting to think that 'Everest' and 'Rock' are both precise designators (if 'Everest' is not is anything?) and that 'Everest is Rock' is nonetheless in some sense indeterminate (Tye, 2000).

The debate over vague identity is concerned with the proper analysis of such examples.

Reflections of Identity in Language Use

The main focus of studies of language and identity in sociocultural anthropology (LISA) is on the interplay between global cultural categories ('census identities' such as gender, race, class, or others that may be culturally salient, such as kinship identities), and how these identities are constructed, performed, or challenged locally in speech events through linguistic forms. One of the distinguishing characteristics of the LISA approach is that rather than taking census and other identity categories as pre-given, it investigates how these categories are made relevant by and for language users. It is important to understand that LISA research does not lose sight of the larger picture; it attempts to discover how speakers' ideologies about census identities shape, and are shaped by, interaction. Identity as viewed in this tradition is therefore emergent but constrained: identities are created and re-created when speakers are actually talking to each other, but the way these identities emerge is contingent on the speakers' sociocultural discourses and ideologies.

Identities are named 'relationships' in cultural ideologies and interactions; identity categories such as census identities are a shorthand for identifying – and thinking about – the many ways that a person relates to others in the community.

identity (Evans, 1978). For if a is only vaguely identical with b, something is true of it – that it is only vaguely identical with b – that is not true of b, so by Leibniz's Law, it is not identical with b at all. Of course, there are vague statements of identity – 'Princeton is Princeton Borough' (Lewis, 1988; 'Princeton' is indeterminate in denotation in standard usage between the township and the borough) – but the conclusion appears to follow that such vagueness is only possible when one or both of the terms flanking the identity sign is an imprecise designator. Reflections of Identity in Language Use

The main focus of studies of language and identity in sociocultural anthropology (LISA) is on the interplay between global cultural categories ('census identities' such as gender, race, class, or others that may be culturally salient, such as kinship identities), and how these identities are constructed, performed, or challenged locally in speech events through linguistic forms. One of the distinguishing characteristics of the LISA approach is that rather than taking census and other identity categories as pre-given, it investigates how these categories are made relevant by and for language users. It is important to understand that LISA research does not lose sight of the larger picture; it attempts to discover how speakers' ideologies about census identities shape, and are shaped by, interaction. Identity as viewed in this tradition is therefore emergent but constrained: identities are created and re-created when speakers are actually talking to each other, but the way these identities emerge is contingent on the speakers' sociocultural discourses and ideologies.

Identities are named 'relationships' in cultural ideologies and interactions; identity categories such as census identities are a shorthand for identifying – and thinking about – the many ways that a person relates to others in the community.

For example, by referring to gender or drawing on a gender identity in interaction, a person calls up a bundle of culturally-shared relationships to other people in their culture. A man may call up solidarity with another man through cultural ideologies of masculinity that identify men as a class of people who share certain social traits. In this sense, identities are 'imaginary' (cf. Anderson, 1991 on imagined communities and nationalism) or 'figured worlds' (Holland *et al.*, 1998). Because identities are relational, a person has no single fixed identity, only identities constructed and contextualized in interaction (and to the extent that an identity is psychologically real, it is based on the self's conception of its place in psychologically idealized models of interaction). LISA studies investigate the tension between ideologies of identity categories and their emergence in interaction through language and other communicative modes. LISA does not study the motivation of speakers to join identity categories, but it does show how such categories are reproduced in ideologies and cultural discourses through talk.

We might suppose that the most straightforward way of claiming an identity is to speak the language of that identity: one is Tongan when one speaks Tongan, Uzbekh when one speaks Uzbekh, etc. But this view is destabilized when speakers are multilingual (which seems to be the larger portion of the world's population). Does a Black-American-Heterosexual-Woman become Dominican when she uses Dominican Spanish, or an Australian when she uses Australian English? By investigating just these kinds of situations (Bailey, 2001) LISA researchers have shown that the 'language-equals-identity' model is too simple to represent actual interaction. This research challenges the notion that languages are single, invariant entities, and has shown that a language is full of many different voices: registers, styles, varieties, and even other languages. At the same time, LISA analyses incorporate speakers' own ideologies of language. For although we might objectively observe that language use is never pure, the subjective ideologies of language users is often quite different. Language users' understandings of "how language is supposed to be" affect the way they use it: they bias performance in certain directions, as sociolinguistic variationists have been able to measure.

The terms most used for such a mixed view of language in LISA are heteroglossia and polyphony, from the work of Russian literary theorist Mikhail Bakhtin. Bakhtin (1981) argued that words (and by extension other linguistic forms) carry the 'voices' of previous uses, into current contexts of use. That is, words have meanings beyond pure denotation and carry the residue of earlier situations of use. Heteroglossia, as Bakhtin uses the term, refers to the tension between the pure official language and more vernacular forms of language existing in a language community and used in a single text. Polyphony refers the use of different languages or varieties that meet on an equal footing (cf. Morris, 1994: 248–249). Bakhtin's focus was the novel, but LISA researchers have shown that heteroglossia and polyphony obtain in everyday conversation, and these properties of language help people to create identities in interaction. This view destabilizes both the simplistic view of 'a language,' and the assumption that by using a particular linguistic feature (e.g., word, pronunciation, or syntactic construction), one can perform an identity connected with a culturally-relevant population that is thought to use that linguistic feature.

Meanings that rely on the current or previous context, or both, are known as indexical meanings. All languages have such indexical meanings as part of their grammar. In English, the meanings of words such as *I* and *you* are associated with actual people only in the moment of speaking. Thai pronouns indicate not only speaker and addressee, but also their relative ages and genders (Simpson, 1997). Most indexical meanings – whether in a grammar or not – relate to the aspect of context that provides information about the speaker's identity. A linguistic feature indexes an identity because someone of that same culturally-relevant identity category has used it before, or has been represented as using it before (e.g., in media). Speakers rarely assert **directly** that they are, for example, a woman, or white, or Bosnian (although they do at times, and these moments are all the more interesting for their rarity). Rather, speakers more often rely on the processes of indexicality to create their identities.

Theorizing indexical meaning as it relates to identity has been the focus of much of the work of Michael Silverstein (1976, 1996) and Elinor Ochs (1992, 1993), who have made a number of important distinctions among indexical meanings that are crucial for understanding how identity and language are theorized. The first distinction is between direct and indirect indexicality (Ochs, 1992). Direct indexicality is a meaning relationship that holds directly between language and the stance, act, activity, or identity indexed. For example, in English, using certain syntactic forms such as imperatives will generally directly index a relationship of power. The imperative is associated with the context of a speaker who has the power to force the addressee to perform the action stated in the imperative. Indirect indexicality arises when the social relationship (in this case, power) is further indexed to an identity category, such as

masculinity. Thus we might notice that men use more imperatives than women, or there might exist (as in the United States) a cultural discourse such that men are supposed to be more authoritative than women. When this supposed connection is discovered, we might be tempted to say that imperatives index masculinity; however, it would be more accurate to say that imperatives indirectly index masculinity because they directly index power, and power is in turn associated with masculinity.

An illustration of this process can be seen in the American English address term *dude* (Kiesling, 2004). *Dude* is used most frequently by young white men, and indexes a stance of casual solidarity: a friendly, but crucially not intimate, relationship with the addressee. This stance of casual solidarity is a stance habitually taken more by young white American men than other identity groups. *Dude* thus indirectly indexes young, white, masculinity as well.

Such descriptions of indexicality are abstract, however, and do not take into account the actual context of speaking, such as the speech event and the identities of the speakers determined through other perceptual modes, such as vision. One of the most difficult aspects of indexicality is that indexes not only call up the previous contexts in which a linguistic feature has been used, but what previous context they call up can be influenced by the current context. Indexical meanings thus interact with the context of speaking, such that the (assumed or 'pre-existing') identity of the speaker can affect the indexicality of a form even as that form is seen as performing an identity. For example, in the United States, often when a women uses an imperative, a particular kind of authority – motherhood – is indexed: when a woman tells a friend (particularly a man) to "put on your coat," the response is often sarcastically, "Yes, mother." In this example, the use of an imperative directly indexes a stance of authority. In the dominant American cultural discourses of femininity, authority is indexed only in the context of motherhood, so this feminine role is indirectly indexed and available for comment by the addressee of the imperative. Such a response is not made when the speaker is known to be a man (unless the addressee wishes to refigure the speaker as a woman for some reason, in which case the layers of indexicality begin to become thick and tangled). One might argue that the content of the imperative is what indexes motherhood: mothers order their children to do things for the children's own good, especially putting on coats. This argument only points out just how specific indexicality can be, however, as a single phrase can call up the stereotypical class of people known in the United States as 'mothers.' In addition, we might observe that imperatives used by women are more often than not used with such 'motherly' content. In any case, note how even such a brief, unremarkable use of language leads to an intricate web of identity indexes. Such are the minute, commonplace, but complex indexical meanings that rely on and recreate identity discourses and ideologies.

These indexicalities are thus both sensitive to and indexical of social context and the other possible relevant identities being performed in a particular instance of talk-in-interaction. Bonnie McElhinny's (1994) study of police officers in Pittsburgh, Pennsylvania, is particularly relevant in this light. She showed that when the identity of being a police officer is salient in an interaction, such a speaker tends to use less affect in her or his speech. This lack of affect indexes a distant, emotionless stance, a stance that is not indexical of femininity in Pittsburgh. However, the women officers told McElhinny that they did not feel less feminine in these situations, because gender is less relevant as an interactional identity; in such interactions they think of themselves primarily as police officers. As women have joined men on the police force, the affectless and emotionless stance has thus come to index not so much masculinity, but 'police officer.'

Further complicating the connections between linguistic form and identity is the fact that indexes are always potentially creative as well as presupposing (Silverstein, 1976). That is, an index can be used to change what is in play in the context (creative) rather than simply respond to the already mutually understood context (presupposing). The classic example of such context-changing uses is that observed by Blom and Gumperz (1972) in Hemnesberget, Norway. In Hemnesberget at that time there was a diglossic situation in which the linguistic variety of Norwegian known as Bokmål was the official language of government and commerce, while Ranamål was the local variety (dialect) more typically used for intimate settings. Blom and Gumperz described an instance in which an inhabitant goes to the community office for official business and interacts with another local inhabitant with whom he is friends. The official business is conducted in Bokmål (indexing in a presupposing manner the situation), but when the official business is finished, the customer switches to Ranamål to indicate he wishes to have a less formal conversation about local matters. This switch from Bokmål to Ranamål is a creative index, because it changes the context from formal to informal, rather than responding to an external cue such as a change of setting or the arrival of a new participant.

While this distinction between creative and presupposing indexicality is important and useful to begin with, LISA researchers have more recently emphasized the fact that indexes always have both a creative and a presupposing aspect. Sidnell (2003), for example, described how language is used to create a male space in a Guyanese rum shop. While this setting is understood by the Guyanese to be a male space, it is nonetheless often populated by women for various reasons. Sidnell analyzed a stretch of talk-in-interaction in which one of the men drinking in the rum shop designs "his talk . . . to preserve the observable gender exclusivity of the activity" (2003: 338). That is, the way his talk is designed makes the space a male one even when he is addressing a woman in it, and thereby helps to recreate the 'male-only' context, in effect (creatively) peripheralizing women who are present.

A final complication comes from the 'level' of knowledge that speakers use in interpreting indexical meaning. While most indexical meanings are not overtly discussed by speakers, some linguistic features nevertheless become the focus of social discussion and overt knowledge. For example, Americans have become aware of, and can articulate, the masculine indexicality of *dude* (they are aware of its use on this societal level), but have much more trouble explaining what it means in terms of local stances. Morford (1997) analyzed the use of second-person pronouns in French in this light. She showed that on one level of indexicality, the use of *tu* and *vous* in French indexes a relationship between two speakers based on a reciprocal vs. asymmetric use of the forms. However, Morford found that French speakers have a knowledge about (for example) what kinds of families have asymmetric use between parents and children, and that some speakers make conscious choices about whether to use *tu* or *vous* with other speakers. Most importantly, these choices have to do with the interplay between this metapragmatic awareness and the kinds of identities that speakers wish to create. Morford cites one particularly vivid example of a teacher who explains that he constructs status as a teacher in part through his asymmetric use of second person address with the support staff of the school.

Performance of Identity in Mediated Social Practice

While the distinctions made above are important, individual indexical forms such as 'pronoun' or 'accent' are idealizations of meanings that are tangled in a messy, changing, and locally contestable web of meaning. That is, there are complex meaning relationships not just between a linguistic form and a specific social identity, but that there are also connections of meaning among different kinds of identities, and different social entities and categories such as institutions and census groups. LISA researchers do not search for psychological representations of such links, but rather they investigate the manner in which such connections are created and used in interaction. In fact, these connections need not be present in any individual's psyche before a speech event; it is by participating in the event itself that speakers bring indexicalities and identities about, because they are needed for speakers to 'make sense' of the talk. In this way, LISA is similar to critical discourse analysis (*see* **Critical Discourse Analysis**) in arguing that the interpretations that speakers make of the ongoing talk based on 'background knowledge' or conversational principles (*see* **Pragmatics: Overview**) are not used in a value-free way but are a resource for doing identity in interaction.

One of the most significant bodies of work along these lines is Jane Hill's (1993, 1995, 1998) work on what she calls "mock Spanish." In this work, the process of indirect indexicality and the ideological structuring of background knowledge come together to reproduce racist discourses that are covert even for those using them. Hill took as her starting point the nonce borrowing of Spanish (or forms that resemble Spanish) by Anglos, such as *Hasta la vista, baby*, popularized by actor and politician Arnold Schwarzenegger in the film *Terminator*. Hill showed that these forms of Spanish are used strategically by speakers to create an ironic speaker stance with respect to stereotypically Hispanic (Latino) identity, stances that are often demeaning to this identity category (e.g., lazy, disorderly, given to rudeness), in effect distancing the self from such identities by gently parodying their principal index, Spanish language forms.

A similar process is at work in a conversation I analyzed between two white American fraternity men (Kiesling, 2001). The two men in that conversation discuss the roster of the fraternity's intramural basketball team. Embedded in this discussion is a short exchange in which each boasts about his basketball ability. At strategic points in both parts of this speech event, the interactants use linguistic features of African American Vernacular English (AAVE) (*see* **English, African American Vernacular**) to index their boasting stance, as well as a stance of basketball expertise. The crucial point is that the men are not trying to 'be black,' but they are drawing on an association of 'blackness' with basketball and boasting. In other words, when performing 'basketball player' it helps to perform 'black' as well.

A similar point was made by Bucholtz (1999), who showed that AAVE features are used in a fight narrative told by a white male high school student in California to represent a tough stance. Other articles appearing in the same journal issue as Bucholtz's made similar points and represent an important body of work for LISA understandings of language and identity.

Issues of race and racism in language, and gender and sexism in language have therefore been central in LISA research. Over the past decade, Susan Gal and Judith Irvine (Gal and Irvine, 1995; Irvine, 2001) have developed an influential set of concepts for understanding how speakers' ideologies of language are involved in the social production of indexicals of identity categories. Their view recognized three semiotic effects of ideology as a factor in indexicality: iconicization, recursivity, and erasure. Iconicization is the ideological endowing of a linguistic feature with and characteristic that is taken to be like some essence of a recognizable identity or type of person. In the example from Hill above, mock Spanish is understood to be iconic of some inherent characteristic, laziness or disorderliness, of Spanish speakers. Recursivity is the manner in which ideologies are represented in parallel recurring form with respect to multiple levels of social organization. In the example above, stereotyped differences between black and white men in the United States (the stereotyped black characteristics of athletic prowess and fighting ability) become the basis for negotiating differences between fraternity brothers, both of whom are white. In effect this use recursively reproduces the black-white identity distinctions in interactions with only white male speakers. Finally, erasure is the effective simplification of both formal and sociological complexities of experience, and can render all but a single term of a schematic dichotomization invisible to speakers. In all of the above examples, the Anglo white language style is invisible as a specifically alternative register, while the Spanish and AAVE are marked and highly salient; the white Anglo vernacular register is erased and re-enforced as normative by such uses, rendering its social peripheralizing power less visible.

Studying Identity through Language and Contextualized Language Variation

Up to this point, we have generally focused on language and identity as performed when speakers use languages or varieties they recognize as different. But the processes of indexicality, and the tendencies toward iconization, recursivity, and erasure are at work even when a single variety is being used, not only when varieties (or languages) are mixed. As sociolinguistic variationists continually remind us, language is inherently variable in both grammar and use (Guy, 1996); such variability is a valuable resource for speakers in identity work. Several researchers have been incorporating insights from LISA studies into the search for how this variability is used by speakers to create social meaning.

Penelope Eckert (2000, 2002) is the most prominent of these researchers and has done the most to move this new perspective of meaning in variation forward. She advocates understanding variation as a resource for creating personal styles and "stylistic practice as a process of *bricolage*, in which ways of being are transformed through the strategic reuse of meaningful resources." (2002: 5) In her ethnographic analysis of sociolinguistic variation in a Detroit-area high school, she showed how vowel variants vary alternately with other aspects of social practice and style, such as 'cruising' (driving around a particular route with friends without a destination) and wearing wide pants cuffs. She showed that while the variables she analyzed have general meanings throughout the school (e.g., whether they are associated with the urban rather than suburban areas of Detroit), they are used in specific clustered ways to create personal styles by individuals.

Students of Eckert's are moving this view of variation and identity forward considerably. Sarah Benor (2001) investigated how the language of Orthodox Jews differs depending on their background and orientation to integrate into the Orthodox community. Her work is significant in two respects. First, it showed that identity is not just about the outward practices and styles of speakers, but that the internal orientations and ideologies of speakers can influence their use of language, and that the relationship between these orientations and language use are not necessarily linear. Second, she showed that adults, as they become integrated socially and ideologically into a new community with a different way of speaking (even if that new way is based on the rate of use of a linguistic variant), can change their speech to the new way of speaking. This finding suggests that speakers have much more control over how they speak than is often assumed. Benor's work showed further the Eckertian view that most variables provide general meaning resources that acquire specific meanings in local contexts, since each analyzes essentially the same linguistic form, but show how its indexicality changes depending on the community and the individual speaker's style.

I have been working with a more atomistic view than Eckert's, but one that is consistent with her perspective. This view focuses on the performance

of stances in interaction rather than personal styles. We can understand Eckert's personal styles to be repertoires of stances; the variables used habitually by speakers to create these styles are primarily concerned with creating stances – relationships of the moment. In an analysis of the *-ing* variable used in a college all-male fraternity in the United States (Kiesling, 1998), I showed that the men who speak with a high rate of the 'standard' velar variant [-ŋ] in meetings are more likely than those whose rate is lower to be taking a stance at that point highlighting their structural power in the fraternity (through age or office-holding). These men also use grammatical forms that help them take an epistemic stance of certainty. Men who use the nonstandard coronal articulation [-n] in meetings tend to take a stance that highlights their connections to the aggregate of men (solidarity) or their ability to work hard for the fraternity. They also tend to use more profanity and other nonstandard features, such as double negatives and *ain't*. The point is that these differing rates of the variable shows the fraternity men to be taking particular stances at various points in specific interactions; it is not just that each man is from a certain class or ethnic background and uniformly reflects that in speech production. Moreover, one can explain why – in the context of the situation, the man's personality, and cultural discourses and ideologies of masculinity, for example – he would take such a stance. This focus on stance moves us further toward an explanation of why speakers use the forms they do, and how these forms mean in interaction.

Such an interactionally local understanding of the indexicality of linguistic forms does not entail that wider cultural discourses, in this case norms of gender, are not also being indexed. In fact, we see here how the meanings of variation also exhibit the property of recursivity: the kinds of stances that the men take, sorting themselves out relationally, are all stances that index masculinity in their culture as well. In other words, they are able to 'be men' of one or another sort – not more or less male – while they are using **either** variant, because the dominant cultural discourses of masculinity include approved types that are both structurally or intellectually powerful (the standard users) and that are friendly or physically powerful (the nonstandard users). These cultural discourses are being recursively played out in the momentary stances the men take in the meetings.

In terms of method, in all of these directions of research, we find a curious marriage between the quantitative, objective, paradigm of variationist linguistics and the qualitative, subjectively-focused view of culture and interaction from sociocultural anthropology. One of the crucial ways that anthropology has informed the study of language and identity is in fact a focus on the speaker's interpretive frameworks, to which we turn now.

Ethnographic Investigation of People's Interpretive Frameworks

One of the strengths of LISA studies is the in-depth investigation of the speakers' interpretive frameworks – how speakers themselves respond to language as reflective or constitutive of identity. This metapragmatic awareness, and its relationship to other indexicalities, is an important area of research in LISA. Silverstein (2001) proposed a classification that specifies under what kinds of conditions, and how, a linguistic form is likely to be accessible to metapragmatic awareness. While there is not space to explain these principles here, Silverstein's work suggested that certain types of linguistic forms are more accessible resources for speakers to use to connect with identities.

Holland and Skinner (1987) took another approach, and argued that identities be understood as organized in the cultural models that speakers hold for the world. Such models are more specific than ideologies; they are in essence normative narratives of life trajectories or domains to which actual people are compared, especially in language. Holland and Skinner used the cultural model concept to understand how women at a southern U.S. college semantically organize the language they use to describe men.

Such interpretations of the relationship between language and identity are beginning to be articulated with traditional dialectological questions about how language relates to place. Johnstone (2004a, 2004b) suggested that a speaker's emplacement – that is, being culturally connected to place – is not simply another census identity, but one that is discursively negotiated like others. Speakers who live in the same geographical space take different orientations to it as a culturally meaningful place, and local dialect forms may function in various ways in everyday talk, in self-conscious performances, and in metalinguistic talk about the dialect, to index these orientations. The use of dialect forms to index orientation to place may help determine which forms are preserved and which are lost over time. This work indicates that even such taken-for-granted categories as place are ideologically organized by speakers, and that this ideological organization can affect the way speakers use language, and its meaning in terms of identities.

Language and Identity over Time

Future research in LISA is likely to focus on further understanding the ways in which indexicality works to create identities in interaction, from a number of perspectives. For one, the question of awareness is still a very open one, in which even what counts as awareness is not entirely clear. One can imagine a typology of awareness that can then be matched with Silverstein's accessibility hierarchy. Awareness may also be promoted by the media as well as face-to-face communication, and it is not clear the ways in which these modes of mediation differ for the creation of identity categories and indexicalities. Finally, the ways in which the use of these indexicalities construct and re-create identity categories, and especially relations of dominance among them, will continue to be a puzzle for some time.

Identity: Second Language

B Norton, University of British Columbia, Vancouver, BC, Canada

© 2006 Elsevier Ltd. All rights reserved.

Interest in second language identity in the field of applied linguistics is best understood in the context of a shift in the field from a predominantly psycholinguistic approach to second language acquisition (SLA) to include a greater focus on sociological and anthropological dimensions of second language learning, particularly with reference to sociocultural, poststructural, and critical theory. Researchers of second language identity have been interested not only in linguistic input and output in SLA, but in the relationship between the language learner and the larger social world. In particular, these researchers have examined the diverse social, historical, and cultural contexts in which language learning takes place and how learners negotiate and sometimes resist the diverse positions those contexts offer them.

Many researchers interested in second language identity are also interested in the extent to which relations of power within classrooms and communities promote or constrain the process of language learning. It is argued that the extent to which a learner speaks or is silent or writes, reads, or resists has much to do with the extent to which the learner is valued in any given institution or community. In this regard, social processes marked by inequities of gender, race, class, ethnicity, and sexual orientation may serve to position learners in ways that silence and exclude. At the same time, however, learners may resist marginalization through both covert and overt acts of resistance. What is of central interest to researchers of second language identity is that the very articulation of power, identity, and resistance is expressed in and through language. Language is thus more than a system of signs; it is social practice in which experiences are organized and identities negotiated.

After tracing the genesis of work in second language identity from the 1970s to the present day, this chapter outlines some of the major theoretical influences on second language identity research. It then examines four trajectories of research that have much promise for the future: identity and investment, identity and imagined communities, identity categories and educational change, and identity and literacy.

The Historical Context

In the 1970s and 1980s, applied linguistics scholars interested in second language identity tended to draw distinctions between social identity and cultural identity. While 'social identity' was seen to reference the relationship between the individual language learner and the larger social world, as mediated through institutions such as families, schools, workplaces, social services, and law courts (e.g., Gumperz, 1982), 'cultural identity' referenced the relationship between an individual and members of a particular ethnic group (such as Mexican and Japanese) who share a common history, a common language, and similar ways of understanding the world (e.g., Valdes, 1986). In my own earlier work (Norton Peirce, 1995), I initially examined identity as a social construct as opposed to a cultural construct because I debated whether theories of cultural identity could do justice to the heterogeneity within the groups encountered and the dynamic and changing nature of identity observed in my research. As Atkinson (1999) has noted, past theories of cultural identity tended to essentialize and reify identities in problematic ways. In more recent years, however, the difference between social and cultural identity is seen to be theoretically more fluid, and the intersections between social and cultural identities are considered more significant than their differences. In this more recent second language research, identity is seen as socioculturally constructed, and scholars draw on both institutional and community practices to understand the

Interest in second language identity in the field of applied linguistics is best understood in the context of a shift in the field from a predominantly psycholinguistic approach to second language acquisition (SLA) to include a greater focus on sociological and anthropological dimensions of second language learning, particularly with reference to sociocultural, poststructural, and critical theory. Researchers of second language identity have been interested not only in linguistic input and output in SLA, but in the relationship between the language learner and the larger social world. In particular, these researchers have examined the diverse social, historical, and cultural contexts in which language learning takes place and how learners negotiate and sometimes resist the diverse positions those contexts offer them.

Many researchers interested in second language identity are also interested in the extent to which relations of power within classrooms and communities promote or constrain the process of language learning. It is argued that the extent to which a learner speaks or is silent or writes, reads, or resists has much to do with the extent to which the learner is valued in any given institution or community. In this regard, social processes marked by inequities of gender, race, class, ethnicity, and sexual orientation may serve to position learners in ways that silence and exclude. At the same time, however, learners may resist marginalization through both covert and overt acts of resistance. What is of central interest to researchers of second language identity is that the very articulation of power, identity, and resistance is expressed in and through language. Language is thus more than a system of signs; it is social practice in which experiences are organized and identities negotiated.

After tracing the genesis of work in second language identity from the 1970s to the present day, this chapter outlines some of the major theoretical influences on second language identity research. It then examines four trajectories of research that have much promise for the future: identity and investment, identity and imagined communities, identity categories and educational change, and identity and literacy.

The Historical Context

In the 1970s and 1980s, applied linguistics scholars interested in second language identity tended to draw distinctions between social identity and cultural identity. While 'social identity' was seen to reference the relationship between the individual language learner and the larger social world, as mediated through institutions such as families, schools, workplaces, social services, and law courts (e.g., Gumperz, 1982), 'cultural identity' referenced the relationship between an individual and members of a particular ethnic group (such as Mexican and Japanese) who share a common history, a common language, and similar ways of understanding the world (e.g., Valdes, 1986). In my own earlier work (Norton Peirce, 1995), I initially examined identity as a social construct as opposed to a cultural construct because I debated whether theories of cultural identity could do justice to the heterogeneity within the groups encountered and the dynamic and changing nature of identity observed in my research. As Atkinson (1999) has noted, past theories of cultural identity tended to essentialize and reify identities in problematic ways. In more recent years, however, the difference between social and cultural identity is seen to be theoretically more fluid, and the intersections between social and cultural identities are considered more significant than their differences. In this more recent second language research, identity is seen as socioculturally constructed, and scholars draw on both institutional and community practices to understand the

conditions under which language learners speak, read, and write the target language.

A brief review of some of the articles published in the special issue of the *TESOL Quarterly* on Language and Identity exemplifies the increasingly interdisciplinary approach to second language identity research characteristic of the 1990s. I argued at the time that while the contributors framed their notions of identity in different terms, the similarities between the conceptions of identity were more marked than their differences (Norton, 1997). Thus Morgan (1997), for example, who was particularly interested in *social* identity, nevertheless explored the relationship between intonation and identity with reference to the dominant *cultural* practices of a particular group of Chinese immigrants in Canada. He did not, however, reify these cultural practices, but sought to understand them in relation to the dynamics of ethnicity and gender. Schecter and Bayley (1997), who were particularly interested in *cultural* identity, nevertheless sought to understand their research with reference to larger *social* debates over the terms of Latino participation in American society, suggesting that social relations of class are important in understanding the relationship between language and identity. Duff and Uchida (1997), indeed, collapsed the distinctions between the social and the cultural by arguing for a sociocultural theory of identity in which identities and beliefs are co-constructed, negotiated, and transformed on a regular basis through language.

The diverse research covered in the 1997 *TESOL Quarterly* special issue, as well as special issues of *Linguistics and Education*, edited by Martin-Jones and Heller (1996), and *Language and Education*, edited by Sarangi and Baynham (1996), anticipated the wide range of research on second language identity characteristic of the early years of the 21st century. A number of monographs on the topic have appeared in catalogs and conferences (Day, 2002; Kanno, 2003; Miller, 2003; Norton, 2000; and Toohey, 2000); a growing body of research, common themes of which are discussed below, have been published in a wide variety of journals including *The Modern Language Journal* (Potowski, 2004), *TESOL Quarterly* (Lam, 2000; Maguire and Graves, 2001), and *Journal of Second Language Writing* (Hyland, 2002; Ramanathan and Atkinson, 1999); and there has been the establishment in 2002 of the award-winning *Journal of Language, Identity, and Education*, edited by Tom Ricento and Terrence Wiley, which has already published an exciting array of research on second language identity.

Current research on second language identity conceives of identity as dynamic, contradictory, and constantly changing across time and place. Indeed, a recurring theme throughout much of the research is that of 'transition.' Many of the participants in research projects on second language identity are undergoing significant changes in their lives, whether moving from one country to another (Kanno, 2003) or from one institution to the next (Harklau, 2000). Such transitions can be productive for language learning, providing learners with enhanced skills at negotiating bilingual identities; other transitions can be more problematic, as learners struggle to accommodate changing expectations in different institutional contexts. In such changing sets of circumstances, identities that might be seen as contradictory may in fact be constructed within contexts that are themselves sites of struggle (Cummins, 2000).

Theoretical Influences

A broad range of theorists have been influential in shaping current research on second language identity, most notable of whom are Bakhtin (1981, 1963/1984), Bourdieu (1977, 1979/1984), Weedon, and Lave and Wenger (1991). All of these theorists, while working within diverse disciplinary frameworks, are centrally concerned with both institutional and community practices that have an impact on learning.

Mikhail Bakhtin (1981, 1963/1984) takes the position that language needs to be investigated not as a set of idealized forms independent of their speakers or their speaking, but rather as situated utterances in which speakers, in dialogue with others, struggle to create meanings. For Bakhtin, the notion of the individual speaker is a fiction, as he sees all speakers constructing their utterances jointly on the basis of their interaction with listeners in both historical and contemporary, and both actual and assumed, communities. In this view, the appropriation of the words of others is a complex and conflictual process in which words are not neutral but express particular predispositions and value systems.

Pierre Bourdieu (1977, 1979/1984), a contemporary French sociologist, focuses on the often unequal relationships between interlocutors and the importance of power in structuring speech. He suggests that the value ascribed to speech cannot be understood apart from the person who speaks and that the person who speaks cannot be understood apart from larger networks of social relationships. In this view, when a person speaks, the speaker wishes not only to be understood, but to be believed, obeyed, and respected. However, the speaker's ability to command the attention of the listener is unequally distributed because of the symbolic power relations between them. To redress the inequities between what Bourdieu calls 'legitimate' and 'illegitimate' speakers, he argues

that an expanded definition of competence should include the "right to speech" or "the power to impose reception" (1977: 648).

The work of Christine Weedon, like that of Bakhtin and Bourdieu, is centrally concerned with the conditions under which people speak, within both institutional and community contexts. Like other poststructuralist theorists who inform her work, Weedon foregrounds the central role of language in her analysis of the relationship between the individual and the social, arguing that language not only defines institutional practices, but also serves to construct our sense of ourselves and our "subjectivity" (Weedon, 1987: 21). Weedon notes that the terms *subject* and *subjectivity* signify a different conception of the individual than that associated with humanist conceptions of the individual dominant in Western philosophy. While humanist conceptions of the individual presuppose that every person has an essential, unique, fixed, and coherent 'core,' poststructuralism depicts the individual (i.e., the subject) as diverse, contradictory, dynamic, and changing over historical time and social space.

A shift from seeing learners as individual language producers to seeing them as members of social and historically constituted communities is of much interest to anthropologists Jean Lave and Etienne Wenger. Lave and Wenger (1991) argue that what they call "situated learning" is an integral and inseparable part of social practice, as newcomers are mentored into the performance of community practices. Their notion "legitimate peripheral participation" represents their view that communities are composed of participants who differentially engage with the practices of their community and that conditions vary with regard to ease of access to expertise, to opportunities for practice, to consequences for error in practice, and so on. From this perspective, then, educational research might focus not so much on assessing individual 'uptake' of particular knowledge or skills, but on the social structures in particular communities and on the variety of positionings available for learners to occupy in those communities.

Rather than seeing language learning as a gradual individual process of internalizing a neutral set of rules, structures, and vocabulary of a standard language, the work of Bakhtin, Bourdieu, Weedon, and Lave and Wenger offers applied linguists ways to think differently about language learning. Such theory suggests that second language learners need to struggle to appropriate the voices of others; they need to learn to command the attention of their listeners; they need to negotiate language as a system and as a social practice; and they need to understand the practices of the communities with which they interact. Drawing on such theory, becoming a 'good' language learner is seen to be a much more complicated process than earlier research had suggested (Norton and Toohey, 2001).

Research Trajectories

Research on second language identity has taken a number of interesting directions that hold much promise. The four trajectories I wish to examine address research on identity and investment, identity and imagined communities, identity categories and educational change, and identity and literacy.

Identity and Investment

In my research with immigrant women in Canada (Norton, 2000; Norton Peirce, 1995), I observed that existing theories of motivation in the field of SLA were not consistent with the findings from my research. Most theories at the time assumed motivation was a character trait of the individual language learner and that learners who failed to learn the target language were not sufficiently committed to the learning process. Such theories did not do justice to the identities and experiences of the language learners in my research. For this reason, I made the case that the notion of 'investment' might help to extend notions of motivation in the field of SLA. The notion of investment, inspired by the work of Bourdieu, signals the socially and historically constructed relationship of learners to the target language and their often ambivalent desire to learn and practice it. If learners 'invest' in the target language, they do so with the understanding that they will acquire a wider range of symbolic and material resources, which will in turn increase the value of their cultural capital. Unlike notions of instrumental motivation, which conceive of the language learner as having a unitary, fixed, and ahistorical 'personality,' the notion of investment conceives of the language learner as having a complex identity, changing across time and space, and reproduced in social interaction. An investment in the target language is best understood as an investment in the learner's own identity.

The notion of investment has sparked considerable interest in the field of applied linguistics (see Pittaway, 2004). McKay and Wong (1996), for example, have drawn on this concept to explain the English language development of four Mandarin-speaking students in Grades 7 and 8 in a California school. They note that the needs, desires, and negotiations of students are not simply distractions or deviations from an ideal language learning situation; on the contrary, they

must be regarded as constituting "the very fabric of students' lives and as determining their investment in learning the target language" (McKay and Wong, 1996: 603). Angelil-Carter (1997) found the concept useful in understanding the language development of an English language learner in South Africa, noting how the student's investment in prior discourses impacted on his acquisition of written academic discourses. Skilton-Sylvester (2002), drawing on her research with four Cambodian women in adult ESL classes in the United States, has argued that traditional views of adult motivation and participation are limited because they do not address the complex lives of adult learners or their investment in learning English. Her findings suggest that an understanding of a woman's domestic and professional identities is necessary to explain the investment in particular adult ESL programs. Potowski (2004) uses the notion of investment to explain students' use of Spanish in a dual Spanish/English immersion program in the United States. She notes that no matter how well-run a language program is, unless a learner's investment in the target language is consistent with the goals of the program, target language growth may not meet expectations. Potowski makes the case that the notion of investment makes an important contribution not only to the study of SLA, but to research on heritage language maintenance.

Identity and Imagined Communities

An extension of interest in identity and investment concerns the imagined communities that language learners aspire to when they learn a new language. In Norton (2001), I drew on my research with two adult immigrant language learners to argue that while the learners were initially actively engaged in classroom practices, the realm of their desired community extended beyond the four walls of the classroom. This imagined community was not accessible to their respective teachers, who, unwittingly, alienated the two language learners who then withdrew from the language classroom. The work of Lave and Wenger (1991) and Wenger (1998) helped me to make sense of this data. In many second language classrooms, all of the members of the classroom community, apart from the teacher, are newcomers to a set of language practices and to a community that includes those language practices in its activities. The question that arises then is what community practices do these learners seek to learn? What, indeed, constitutes 'the community' for them?

For many language learners, the community is one of the imagination – a desired community that offers possibilities for an enhanced range of identity options in the future. The community may also be, to some extent, a reconstruction of past communities and historically constituted relationships. In essence, an imagined community assumes an imagined identity, and a learner's investment in the target language must be understood within this context. Learners have different investments in particular members of the target language community, and the people in whom learners have the greatest investment may be the very people who represent or provide access to the imagined community of a given learner. Of particular interest to the language educator is the extent to which such investments are productive for learner engagement in both the classroom and the wider target language community. Such questions have been taken up more extensively in a coedited special issue of the *Journal of Language, Identity, and Education* on Imagined Communities and Educational Possibilities (Kanno and Norton, 2003) in which Adrian Blackledge, Diane Dagenais, Farah Kamal, Yasuko Kanno, Bonny Norton, Aneta Pavlenko, and Sandra Silberstein explore the imagined communities of specific groups of learners in Canada, Japan, Pakistan, the United Kingdom, and the United States.

Identity Categories and Educational Change

While much research on second language identity explores the multiple and intersecting dimensions of learners' identities, there is a growing body of research that seeks to investigate the ways in which particular relations of race, gender, class, and sexual orientation may have an impact on the language learning process (Norton and Toohey, 2004). Innovative research that addresses these issues does not regard such identity categories as variables, but rather as sets of relationships that are socially and historically constructed within particular relations of power. Ibrahim's (1999) research with a group of French-speaking continental African students in a Franco-Ontarian High School in Canada explores the impact on language learning of 'becoming black.' He argues that the students' linguistic styles, and in particular their use of Black Stylized English, was a direct outcome of being imagined and constructed as Black by hegemonic discourses and groups. From a slightly different perspective, Taylor's (2004) research in an anti-discrimination camp in Toronto, Canada, argues for the need to understand language learning through the lens of what she calls *racialized gender*. The stories of Hue, a Vietnamese girl, and Khatra, a Somali girl, are particularly powerful in this regard, supporting the view held by Kubota (2004) that a color-blind

conception of multiculturalism does not do justice to the challenges faced by language learners of diverse races and ethnicities.

Similarly, the work of scholars such as Ehrlich (1997) and Pavlenko (2004) is particularly insightful with regard to intersections of gender and language learning. Their conception of gender, which extends beyond female-male divides, is understood to be a system of social relationships and discursive practices that may lead to systemic inequality among particular groups of learners, including women, minorities, elderly, and disabled. Pavlenko, for example, argues for the need to understand the intersections between gender and other forms of oppression, noting that both girls and boys who are silenced in the language classroom are more likely those from the working class. In a similar spirit, Nelson (2004) explores the extent to which sexual orientation might be an important identity category in the second language classroom. Of central interest is the way in which a teacher can create a supportive environment for learners who might be gay, lesbian, or transgendered. Interest in identity categories and language learning is gaining momentum. A special issue of the *TESOL Quarterly* on Gender and Language Education, edited in 2004 by Kathy Davis and Ellen Skilton-Sylvester as well as an edited volume *Gender and English Language Learners* (Norton and Pavlenko, 2004) are available.

Identity and Literacy

Researchers of second language identity have become interested not only in the conditions under which language learners speak, but in the extent to which identities and investments structure their engagement with *texts*. There is growing recognition that when a second language learner reads or writes a text, both the comprehension and construction of the text is mediated by the learner's investment in the activity and the learner's sociocultural identity. By way of example, Norton Peirce and Stein (1995) demonstrate how the meaning of a South African reading comprehension text shifted when the social conditions under which it was read changed. They argue that the changing social occasions created different kinds of investments on the part of the students, and as the students' identities shifted from compliance to resistance, so did their interpretation of the text. Student resistance is also a theme in Canagarajah's (2004) literacy research with Tamil students in Sri Lanka and African American students in the United States, in which he demonstrates how students learning a second language or dialect sometimes engage in clandestine literacy activities to resist unfavorable identities imposed on them.

Much emerging research on literacy and second language identity also addresses the impact of literacy practices on relationships beyond the classroom. Lam (2000), for example, studied the Internet correspondence of a Chinese immigrant teenager in the United States who entered into transnational communication with a group of peers. She demonstrates how this experience of what she calls *textual identity* related to the student's developing identity in the use of English. The research of Kramsch and Thorne (2002) indicates, however, that not all transnational Internet communication leads to positive identity outcomes. In their study of the synchronous and asynchronous communication between American learners of French in the United States and French learners of English in France, they found that students had little understanding of the larger cultural framework within which each party was operating, leading to problematic digital exchanges. Ramanathan and Atkinson (1999), indeed, make the case that there is much need for cross-cultural writing research to better inform both teachers and students of the sociocultural knowledge of student writers from diverse regions of the world.

Scholars such as Luke (2004), Kress (1993), and Ivanič (1997) have influenced much research on the relationship between literacy and second language identity. While Luke's work has focused on the contribution of critical literacy to second language education and Kress's on the conception of text as a socially and historically constituted genre, Ivanič has explored the notion of writer identity, making the case that writers' identities are constructed in the possibilities for self-hood available in the sociocultural contexts of writing. Ivanič's distinctions between the "autobiographical self," the "discoursal self," and the "authorial self" have been useful in writing research with both young second language learners (Maguire and Graves, 2001) and college-level students (Hyland, 2002; Starfield, 2002).

Conclusion

Research on second language identity has struck a chord in the field of applied linguistics, opening up multiple avenues for research on every aspect of the field. While this chapter has focused on the identity of the second language learner, there is now increasing interest in the identity of the second language teacher (Johnston, 2002; Lin, 2004), the second language teacher educator (Goldstein, 2003; Pennycook, 2004), and the second language researcher (Hawkins, 2004; Leung *et al.*, 2004). If we take seriously the argument that the identity of the second language

learner is not a personality variable but a socially and historically constructed relationship to both institutional and community practices, then it follows that teachers, researchers, administrators, testers, and policy makers are all implicated in the range of identities available to the second language learner. There is every indication that the interest in second language identity will grow in momentum, enriching existing trajectories of research and forging new, exciting directions.

Ideophones

Introduction

The study of ideophones dates back to the end of the 19th century, but it was especially influenced by Diedrich Westermann (1927, 1937) who examined the sound symbolism of a special class of onomatopoeic words called 'Lautbilder' ('*sound pictures*') in West African languages, which "describe an object or denote an event as a whole" (Westermann, 1937: 159).

Until the late 1970s, ideophones were almost exclusively described for African languages, but no ideophones were reported for languages of the Khoisan family. In recent years, an increased interest in ideophones has provided us with detailed studies in Khoisan, as well as in European, Asiatic, Australian, and Amerindian languages (cf. Asher, 1982; Nuckolls, 1996; Kita, 1997; Alpher, 2001; Voeltz and Kilian-Hatz, 2001) so that it is now established that the existence of ideophones is not restricted to some African language families but seems to be a universal feature of human language. Examples of ideophones are in English *wop, wiggle-waggle, tic-tac, ding-dang-dong, ptt ptt ptt* or in Southern Sotho (Sotho, Southern) *nele* ('disappear and be silent for a long time'), *shwɛrɛrɛ* ('tell lies'), *ɲɛkɛthɛ* ('have a salty taste'), *hlanahlana* ('fly up and down and from side to side'), and *tlɔpɔrɔ* ('be straight') (Kunene, 1978: 50ff.).

Ideophones

Introduction

The study of ideophones dates back to the end of the 19th century, but it was especially influenced by Diedrich Westermann (1927, 1937) who examined the sound symbolism of a special class of onomatopoeic words called 'Lautbilder' ('*sound pictures*') in West African languages, which "describe an object or denote an event as a whole" (Westermann, 1937: 159).

Until the late 1970s, ideophones were almost exclusively described for African languages, but no ideophones were reported for languages of the Khoisan family. In recent years, an increased interest in ideophones has provided us with detailed studies in Khoisan, as well as in European, Asiatic, Australian, and Amerindian languages (cf. Asher, 1982; Nuckolls, 1996; Kita, 1997; Alpher, 2001; Voeltz and Kilian-Hatz, 2001) so that it is now established that the existence of ideophones is not restricted to some African language families but seems to be a universal feature of human language. Examples of ideophones are in English *wop, wiggle-waggle, tic-tac, ding-dang-dong, ptt ptt ptt* or in Southern Sotho (Sotho, Southern) *nele* ('disappear and be silent for a long time'), *shwɛrɛrɛ* ('tell lies'), *ɲɛkɛthɛ* ('have a salty taste'), *hlanahlana* ('fly up and down and from side to side'), and *tlɔpɔrɔ* ('be straight') (Kunene, 1978: 50ff.).

Most students of ideophones still refer to the definition given by Clement Doke (1935: 118), who created the term 'ideophone' according to their function in Bantu languages as a "vivid representation of an idea in sound. A word, often onomatopoeic, which describes a predicate, qualificative or adverb in respect to manner, colour, sound, smell, action, state or intensity." There are, however, no formal criteria that define a word class of ideophones crosslinguistically. Therefore, there still exists confusion on how to classify ideophone-like words in a given language. The consequence is that ideophones are either ignored in grammars and/or if they are described at all, such descriptions consist only of a word list, or the study concentrates on a language internal analysis. Two methodological approaches can be distinguished, which are summarized in the following sections.

Formal Approach

Similar to interjections, ideophone-like words behave differently than the well-known classes of nouns, verbs, adjectives, or adverbs, because they may be phonologically aberrant and are mostly morphologically invariable *simplicia*. Despite such formal anomalies compared to other word classes, ideophones syntactically parallel them in some respect, so that it is not always clear in a given language if they should be interpreted as a phonological and/or morphological aberrant subclass of other lexical word classes or if they form a word class of their own. Ideophones may occupy the slot of a verb, noun, adverb, or adjective in the sentence where they are embedded. In some languages, their distribution may be restricted to only one of these positions, and they are, therefore, categorized as subclass(es) of those words which they replace. They form a subclass of nouns, e.g., in Somali (Tosco, 1998: 129), of verbs, e.g., in Tsonga (Marivate, 1985: 214), or of adverbs, e.g., in Yagua (Payne and Payne, 1990: 457). In most languages, however, two or more such syntactic functions may be assigned to them, depending on which slot they occupy. They may be adjectives, adverbs, and verbs in Wolaitta (Wolaytta) (Amha, 2001: 56ff.), and in Pastaza Quechua (Quechua, Pastaza, Southern) they may be used as adverbs, verbs, nouns, adjectives, or intensifiers (Nuckolls, 1996: 9f, 141f.). They behave similarly in Gbaya-Bogoto so that Péli (1991/2: 30) characterizes their syntactic behavior as extremely mobile and flexible. Ideophones that are categorized as a subclass are often described under various different terms like 'nonverbal verbs' (Marivate, 1985: 214), or 'ideophonic verbs, nouns and adverbs' (Newman, 1968).

Based on these language specific descriptions, only a few efforts have been made to extract formal criteria that may be common to a word class ideophone crosslinguistically. In Bantu languages, ideophones form a more coherent class of words syntactically than in other language families. Based on Doke's functional definition given above, Samarin (1971) compares ideophones in a survey of over 150 Bantu languages and draws up a list of formal features that are common to ideophones in Bantu. These include a predictable derivation of ideophones and striking parallels with verbs that often differ from ideophones only in a predictable final vowel. Whereas this list is an instrument to differentiate ideophones from other word classes in Bantu, not all of these features are applicable to languages of other language families. This is confirmed by Childs (1987, 1994) in a survey of ideophones in African languages, where he lists some properties of ideophones, like sound-symbolism, possible phonetic anomalies and violations of phonological rules, the lack of morphology except for reduplication or vowel lengthening, the fact that they are apart from the syntax of the surrounding utterance that is called "syntactical aloofness" by Kunene (1978), and finally, their close connection to gestures. However, no feature seems to be unique to ideophones crosslinguistically (Childs, 1994: 182), and no feature is shared by all ideophones in a specific language, so that ideophones may better be described in a prototype approach (Childs, 1987).

Discourse Pragmatic Approach

Because formal properties alone may not be sufficient to separate ideophones from other words, other investigators highlight their sound-symbolic nature, which is connected to their special pragmatic function in discourse. Most authors assign a special expressive function to ideophones or characterize them as part of an expressive register. Therefore, they are named 'expressive adverbs,' e.g., in Bambara (cf. Dumestre, 1981), 'expressive onomatopes' in Urubu-Kaapor (Urubú-Kaapor) (cf. Kakumasu, 1986), or simply 'expressives,' e.g., in Semai (cf. Diffloth, 1976). Ideophones consist of a combination of motivated sounds that imitate an event rather than to describe it. Fortune (1962: 6) characterizes ideophones in Shona as part of the event level in being "a vivid re-presentation or re-creation of an event in sound." Similarly, Kunene (1978: 3ff.) focuses in his study on the shift of participant roles whereby the speaker becomes the actor of the ideophonic event and the hearer becomes a witness. Kock (1985: 52) claims

that the communicative purpose of ideophones is to actualize the event which it describes. And Nuckolls (1996: 12) states that "the distinction between a speech event and a narrated event is blurred [because] the speech event *becomes* the narrated event." Kita (1997) finally sees Japanese ideophones, which he calls 'mimetics,' as part of the affecto-imagistic dimension, which is complementary to the analytic dimension containing descriptive information. From this perspective, ideophones are not just expressive variants of other words but are a complementary mode or dimension of speech.

Whereas the slot that an ideophone occupies in the sentence was a major criterion for its syntactic categorization as subclass of verbs, nouns, adverbs, or adjectives, Kunene (1978) rejects this argument as misleading. According to him, the assignment of such a syntactic function seems merely triggered by the translation into the reference language. He demonstrates in Southern Sotho that the semantics and function of ideophones remain the same in all kinds of various syntactic environments, being invariably a 'dramaturgic predicate,' even if its position might change; therefore, ideophones are 'syntactical aloof' from the rest of the sentence.

Based on Kunene's thesis that ideophones behave pragmatically *and* grammatically differently, the study of Kilian-Hatz (1999) represents the first typological attempt to define a word class 'ideophone' crosslinguistically. In combining formal, sound-symbolic, and pragmatic features shared by ideophone-like words in 138 languages of the world, an ideophone is defined as a proper word class that is complementary to descriptive word classes of the analytic dimension (i.e., nouns, verbs, adjectives, and adverbs) on the one hand and to the purely appellative interjections and exclamations on the other hand. Other than descriptive words, ideophones convey another mode of perception by simulating an immediate sensory experience of an event that hearer and speaker share with each other; this creates a social intimacy of the speaker community (cf. Nuckolls, 1996: 12ff.), which is a characteristic of informal speech and an expressive language register, where ideophones are exclusively found. The simulation of an event implicates that the event takes place in the imagination, and thus, ideophones are inherently affirmative in nature and are not subject to negation or interrogation.

The semantic concepts of ideophones vary from audible, visible, and tactile perceptions, as well as smell and psychological states, but a language contains at least audible ideophones. An interesting areal phenomenon is that the intension of colors like 'bright white' or 'bright red' is expressed by ideophones in African languages and in Malagasy. In contrast to words of the analytic register, each denoting only a part of an event, an ideophone denotes an event as a whole and represent an independent, complete sentence- or clause-like utterance, which forms its own intonation unit (Kilian-Hatz, 1999: 234 ff.).

Comparable to a live broadcast on the radio, the speaker, by using ideophones or direct speech, raises the illusion that the verbalized event or situation happens simultaneously at the moment of its production/pronunciation. In this perspective, speech level and event level are identical (cf. von Roncador, 1988, who terms this kind of level shift 'Referenzverschiebung' ('*shift of reference*') on which his definition of direct speech is based). Ideophones and direct speech differ only insofar as direct speech quotes a speech act, whereas ideophones report an extralinguistic event like a sound, a smell, a taste, a visual impression, a movement, or a psychic emotion. Due to the striking formal and functional parallels of direct speech with ideophonic clauses, the latter are even defined as a special form of direct speech; cf. Voeltz (1971) and Kunene (1978) for Bantu languages and, more generally, von Roncador (1988: 125). Like utterances of direct speech, ideophones are either obligatorily or optionally introduced into the context by a *verbum dicendi,* as demonstrated in ex. (1) from Southern Sotho and/or by a complementizer as in ex. (2) from Tamil.

Southern Sotho

(1a)	bá	thóla	bá-re	tú.
	they	*kept quiet*	*they say/do*	*tu*

Or:

(1b)	bá	thóla	*tú*.
	they	*kept quiet*	*tu*

'They kept quiet – (they kept) dead-quiet' (Kunene, 1978: 29).

Tamil

(2)	Ava	**kupu kupu**-ŋŋu	aʐutaa.
	she	QUOT	*weep*.PAST.3sg.F

'She wept with a sobbing sound' (Asher, 1982: 242).

Alternatively, a small set of so-called dummy verbs (cf. Childs, 1994: 187f) like 'do,' 'give,' 'go,' 'have' and 'be/become' as in English '*The cork cried/went pop*' (Oswalt, 1994: 302) or a perception verb like 'hear,' 'see,' 'smell,' 'taste,' etc., as in the Zulu ex. (3) is used to introduce ideophones into the context. Another way to embed the ideophonic utterance similar to direct speech in a narrow sense is by an

introduction that is shortened to an agent, as in the examples (4) and (5).

Zulu

(3) Niyamuka **mfo.**
you.PRES.*smell* *of evil smell*
'You smell bad' (Voeltz, 1971: 147).

Gbaya

(4) Wanto **záďáďá**
W. *adamant*
'Wanto was adamant' (Noss, 1986: 253).

Yir-Yoront (Yir Yoront)

(5) Ngoyo **kʊt!**
'I [spread it], kat!' (Alpher, 1994: 168).

As with a clause of direct speech, grammatical relations between an ideophonic clause and other constituents of the descriptive context are not expressed morphologically. Ideophones are syntactically aloof and invariable. The interaction of ideophones and descriptive context takes place on the narration level where the descriptive text is interrupted by ideophonic utterances. The descriptive context can be understood as the frame wherein the ideophonic event is realized. Ideophones may be integrated by two ways into the context. In the first type of integration, they may replace a descriptive sentence or clause. In this context, ideophones are completely isolated, as demonstrated in ex. (6), taken from the Adamawa-Ubangi language Baka with a series of ideophones, or they form one clause in a series of clauses, as in the English example '*Our eyes met.* ***Zing.*** *Cupid!*' (Oswalt, 1994: 302).

Baka

(6) **Wòàwòàwòàwòà,** **pɔ̀ɔ̀,**
the hunters are discussing — the chimpanzee interrupts eating
kung, **wóoò,**
a spear strikes the chimpanzee — the chimpanzee falls down
pao, **tung.**
the chimpanzee breaks a branch — hard falling the chimpanzee arrives on the ground
(Kilian-Hatz, 1999: 29).

In the second type of integration into the context, the ideophone accompanies a verb, adverb, adjective, or even a clause like a nonverbal gesture by either anticipating it as in (7a) or by being a paraphrase in apposition to it as in (7b) and as in the German ex. in (8)

Gbaya

(7a) **Rut**, a yeé kɔ.
'Flash, it entered a hole' (Noss, 1986: 251).

(7b) A yeé kɔ **rut.**
'It entered a hole **rut** (like a flash)' or 'It entered a hole – flash' (ibid.).

German

(8) Da knallt **—peng—** die Tür.
there *bang*.3sg.PRES *bang* *the* *door*
'There the door bangs: Bang.'

Languages differ typologically in that ideophones (a) may be used preferably with, or are even restricted to accompany, only one kind of phrase (e.g., a noun phrase or a verbal phrase) or (b) may replace or accompany more than one or even all kinds of phrases and clauses, as is the case in most Bantu languages. From this perspective, ideophones that are categorized as a subclass of adverbs, e.g., in Yagua (Payne and Payne, 1990: 457) in the formal approach, may be interpreted as ideophonic clauses that are paraphrases in apposition to or anticipating a verbal state or event.

Unlike descriptive words, ideophonic utterances consist of one word only wherein the whole information is bundled synthetically. Their special performative function of verbalized dramatization is achieved by the inherent sound-symbolic nature of ideophones. Information is encoded in language-specific, sound-symbolic submorphemic units that may consist of a syllable, a sound, or a tone that follow each other iconically according to the sequence of single components of an event (cf. Weakly, 1977). According to Rhodes (1994), such submorphemes may be phonetically realized in either a 'wild' or merely a 'tame' manner by means of a speaker-dependent preference to express only one or more than one nuance of an event in one submorpheme. This realization may lead to phonological anomalies. Here it is noteworthy that only the so-called 'tame' ideophones are prone to change the word class and may derive into nouns or verbs, or vice versa.

Idiolect

K Hazen, West Virginia University, Morgantown, WV, USA

© 2006 Elsevier Ltd. All rights reserved.

Definitions

The term *idiolect* refers to the language of an individual. It is etymologically related to the Greek prefix *idio-* (meaning own, personal, private, peculiar, separate, distinct) and a back-formation of *dialect*. Its specific meanings predominantly fall in two categories:

- The sum total of language of one person, including all possible utterances.
- The linguistic output of one person (i.e., only what that person says and not the internal knowledge in the mind). For some scholars, emphasis here is on the constellation of language variation patterns which distinguish an individual from other speakers of the same dialect.

The additional restriction for these two definitions is time; a person's idiolect may be constrained to one particular time, thus partially equating *idiolect* with *style*. The term *idiolect* is often invoked to define a dialect as an aggregation of idiolects, either as an abstraction or as a mathematical average. Thus, some claim that idiolects are the only real linguistic objects, but others dispute this claim, arguing instead that the regularity of grammar appears at the level of dialect. Despite its apparent creation as a scientific term, it has been embraced by nonlinguists, often

Definitions

The term *idiolect* refers to the language of an individual. It is etymologically related to the Greek prefix *idio-* (meaning own, personal, private, peculiar, separate, distinct) and a back-formation of *dialect*. Its specific meanings predominantly fall in two categories:

- The sum total of language of one person, including all possible utterances.
- The linguistic output of one person (i.e., only what that person says and not the internal knowledge in the mind). For some scholars, emphasis here is on the constellation of language variation patterns which distinguish an individual from other speakers of the same dialect.

The additional restriction for these two definitions is time; a person's idiolect may be constrained to one particular time, thus partially equating *idiolect* with *style*. The term *idiolect* is often invoked to define a dialect as an aggregation of idiolects, either as an abstraction or as a mathematical average. Thus, some claim that idiolects are the only real linguistic objects, but others dispute this claim, arguing instead that the regularity of grammar appears at the level of dialect. Despite its apparent creation as a scientific term, it has been embraced by nonlinguists, often

with positive connotations of individual personal expression.

Precedent for *Idiolect*

Although the term itself did not appear until 1948, the concepts behind the term have been a part of linguistic scholarship since the end of the 19th century.

The *Junggrammatiker* in general and specifically Paul, in *Prinzipien der Sprachgeschichte,* argued against the metaphor of languages as living organisms, instead advocating the locus of language in the minds of individuals. Paul disputed *Völkerpsychologie* and conversely implemented terms such as *individuellen Sprechtätigkeit, individuelle Verschiedenheiten, individuellen Sprachen,* and *individuelle Unterschiede.* Modern interpretations of Paul's work now employ *idiolect* in discussing his ideas.

In contrast to the *Junggrammatiker,* Saussure (1972: 30) deemphasized diachronic analysis in favor of synchronic analysis, but he retained the concept of the individual locus of language: "... l'exécution n'est jamais faite par la masse; elle est toujours individuelle, et l'individu en est toujours le maître; nous l'appellerons la *parole.*" Saussure (1972: 141) does use the prefix *idio* when discussing the focus of synchronic linguistics: "L'objet de la linguistique synchronique générale est d'établir le principes fondamentaux de tout système idiosynchronique ...." It is not clear whether such uses prompted any coining by later writers, but these concepts found a stable home in the term *idiolect.*

The first use of the term *idiolect* is by Bernard Bloch (1948: 7) in revising a set of postulates by Leonard Bloomfield: "The totality of possible utterances of one speaker at one time in using a language to interact with one other speaker is an *idiolect* .... Our definition implies (a) that an idiolect is peculiar to one speaker, (b) that a given speaker may have different idiolects at successive stages of his career, and (c) that he may have two or more different idiolects at the same time." Bloomfield himself had captured the concept of idiolect in writing: "If we observed closely enough, we should find that no two persons – or rather, perhaps, no one person at different times – spoke exactly alike" (1933: 45). Bloch coined the term in order to establish a locus for language inside the larger abstractions of speech community and language.

Usage

Like terms such as *language* and *dialect,* the meaning and import of *idiolect* can be contentious at times. One specific debate has been whether idiolects are the real object of linguistic scholarship or not.

Weinreich *et al.* (1968) essentially banished the term from sociolinguistics when they strongly opposed the nested view of language whereby an aggregate of idiolects make up a dialect. Instead, they argued that only the grammar of the speech community had consistent patterns and that individuals acquired their patterns from the speech community grammar. Weinreich *et al.* (1968) associated the term *idiolect* with Paul and Saussure: "...we will dwell on Hermann Paul, who apparently was the first to isolate the language of the individual as the most legitimate object of linguistic study. We will trace the hardening of the paradox in the Saussurean period, when homogeneity of language – assumed to be found in the idiolect – was drawn upon as a prerequisite for analysis." Thus, within sociolinguistics, language variation patterns of individuals were not often studied except when aggregated to approximate and reveal the language variation patterns of the speech community.

At the end of the 20th century, variationists began again to study specifically the language variation patterns of individuals and, at times, use the term *idiolect.* Nahkola and Saanilahti (2004: 75) employed *idiolect* in a real-time study of diachronic variation where they focused on change over the life of individuals (e.g., "Our study suggests that categorical linguistic features are inclined to remain categorical in the idiolect"). Here, they employ the second sense of the term above.

Idiom Dictionaries

D Dobrovol'skij, Russian Academy of Sciences, Moscow, Russia

© 2006 Elsevier Ltd. All rights reserved.

There exist numerous dictionaries of idioms for practically all languages, covering a more or less long literary tradition (see the select bibliography at the end of this article). Obviously, it is not possible to describe here all these dictionaries in detail. So this article will instead concentrate on some linguistic problems in the basic prerequisites for compiling idiom dictionaries, and show how various dictionaries solve these problems.

The first question that must be answered by idiom dictionaries concerns the very notion of idiom. When working on such a dictionary, the lexicographers have to know exactly what they understand by 'idiom,' otherwise they would face serious difficulties deciding which expressions should be included and which should not. Also, the users have the right to know what they can expect to find in a given dictionary. Though idiom research has quite a long tradition and has become an internationally developed linguistic discipline today, we are still far from being able to give a definite and generally accepted answer to the question 'what is an idiom?' Consequently, this is the first question to be discussed in this article. The second question faced by every dictionary of idioms is 'what are the specifics of idiom semantics and pragmatics?' Without answering this question it is hardly possible to develop an adequate entry structure.

Idioms as a Special Type of Phraseme

There are both objective and subjective factors which make the inventories of expressions included in various 'dictionaries of idioms' somewhat incomparable. These factors can be divided into two groups:

- factors due to different interpretations of the notion of idiom;
- factors due to different interpretations of the needs of the user.

As far as first group is concerned, the reasons for relevant differences may lie both in different terminological traditions and in different theoretical foundations adopted by lexicographers. Here I can only touch on the main terminological problems. Recently, there was published a list of about 70 terms that have appeared in different fields of research to describe phrasemes and related phenomena (though some of them do not mean exactly the same thing), such as 'coordinate constructions,' 'collocations,' 'complex lexemes,' 'fixed expressions,' 'formulaic language,' 'lexical(ized) phrases,' 'multiword lexical phenomena,' 'phraseologisms,' 'phrasemes,' 'phraseological items,' 'ready-made expressions,' 'set phrases,' 'stock utterances,' and many more (cf. Wray, 2002: 9). Here I use the term 'phraseme' as a hypernym for all kinds of phrasal lexical items, figurative as well as nonfigurative.

In spite of the terminological chaos, there is a consensus about the main features of phrasemes. According to the most general definition, phrasemes are conventional multiword units of the lexicon showing various kinds of formal and/or semantic irregularities. Phrasemes are stable by definition: as soon as an expression has become conventionalized, it will be reproduced in discourse as a prefabricated unit of language (cf. Burger *et al.*, 1982: 1). In other words, phrasemes are multiword units of the lexicon, and as such they are, like all lexical units, relatively stable in form and meaning.

Thus, all phrasemes are subject to lexicographical description. The question is, however, should they be described in one dictionary or should a special dictionary be developed for every type of phraseme? In principle, both ways are possible. Older traditional phraseological dictionaries were often just mixed collections of different types of phrasemes, proverbs, and other more or less fixed expressions; see, for example, Stoett (1974) and Ter Laan (1983) for Dutch; Mikhel'son (1984) for Russian; Lapucci (1969) for Italian; Koskimies (1906) and Kuusi (1988) for Finnish. Even if it has the word 'idiom' in the title it does not mean that such a work includes exclusively idioms in the strict sense of this term. The current trend in lexicography, and linguistics in general, is one towards more specific dictionaries. This also applies to phraseological dictionaries; compare dictionaries of idioms in a strict sense, such as Molotkov (1986), Moon (1995), Longman (1998), Spears (2000), Duden (2002), and Baranov and Dobrovol'skij (forthcoming). For dictionaries of this kind the question of the distinctive features of idioms is of decisive importance.

There is a long tradition in lexicon research of classifying phrasemes into classes such as restricted collocations, phrasal verbs, routine formulae, idioms, proverbs, and the like. The consensus here is that the central group of phrasemes is that of idioms. A crucial property of idioms is their semantic irregularity

(or idiomaticity), which is closely related to the property of figurativeness. Furthermore, it is generally agreed that idioms, for the most part, are not frozen elements of a language and that they are usually arbitrary only from the point of view of their production, but not from the perspective of their understanding, because most of them are clearly motivated by underlying structures of knowledge (for more detail see Dobrovol'skij and Piirainen, 2005). Still there is no general consensus about where to draw the line between idioms and other phraseme types (*see* **Idioms**). The differences between various linguistic schools concerning the extension of idiom class are (at least, to a certain extent) due to different terminological traditions in different languages. So, in English the term 'idiom' can be traditionally used in the sense of 'phraseme,' i.e., it may be understood as an umbrella term for all possible fixed expressions. This use is very uncommon in Russian or German, so that if the term 'idiom' is used the German and Russian readers are normally aware of the fact that a given dictionary contains exclusively idioms in a strict sense. Here we see that a seemingly scholastic problem has practical lexicographic consequences.

What place do idioms occupy in the large class of phrasemes? It would be desirable that the theoretical model of idioms be as close as possible to the 'natural' way most linguists (and, above all, most lexicographers) understand this category. The linguists' understanding is based on the idea that idioms are the most irregular category among phrasemes. Since, in terms of idiomaticity theory (cf. Baranov and Dobrovol'skij, 1996), irregularity manifests itself through idiomaticity and stability, these features must be more salient and represented more explicitly in idioms than in other phrasemes.

Idiomaticity is understood as a semantic reinterpretation and/or opacity, while stability is understood as frozenness or lack of combinatorial freedom of a certain expression. Idioms can be thus defined as phrasemes with a high degree of idiomaticity and stability. In other words, idioms must be fixed in their lexical structure (however, this does not exclude a certain variation), and they must be, at the same time, semantically reinterpreted units (i.e., they do not point to the target concept directly but via a source concept) and/or semantically opaque. So, *tilt at windmills*, *drive someone into a corner*, or *(as) dead as a doornail* are idioms, and *make/take a decision*, *accept the challenge*, *strong coffee*, or *heavy rain* are not because the former expressions are more irregular than the latter ones. The current approaches to phraseology also distinguish between proverbs (e.g., *every dog has its day* or *beggars can't be choosers*) and idioms with sentence structure (also called sentence idioms or speech formulae; e.g., *the coast is clear* or *the die is cast*). The distinguishing features are to be found on different levels: in the type of semantics, in pragmatics, and in the semiotic status of sentence idioms vs. proverbs.

As far as the factors of the second group are concerned, i.e., the different interpretations of the needs of the user, they influence the structure of idiom dictionaries no less than the differences in understanding the notion of idiom. Differences in the number of entries are often due to the fact that some dictionaries focusing on idioms also include current proverbs and sayings (Kari, 1993; Lubensky, 1995; Beltrán and Yáñez, 1996; Van Dale, 1999; Bárdosi, 2003; Forgács, 2003), as well as some collocations (Cowie *et al.*, 1993; Lubensky, 1995; Petermann *et al.*, 1995).

Differences of this kind may also be due to the attitude toward less common idioms, e.g., obsolete or old-fashioned expressions. Compare dictionaries which are trying to cover the entire range of idioms, such as Schemann (1993), Lubensky (1995), Van Dale (1999), Duden (2002), or Rey and Chantreau (2003), on the one hand, and smaller dictionaries concentrating on relatively frequent present-day idioms (Moon, 1995; Dobrovol'skij, 1997; Lurati, 2001), on the other. A special lexicographic type is represented by dictionaries which include current usage only, but do not restrict themselves to frequent expressions, such as the corpus-based Baranov and Dobrovol'skij (forthcoming) with some 7000 entries drawn from texts between 1960 and 2003. Of course, this dictionary is not an exception. Many present-day dictionaries with a sound theoretical background are based on large collections of evidence of actual usage, e.g., Cowie *et al.* (1993), Moon (1995), and Forgács (2003), just to name a few.

Another parameter concerns the register of included expressions. Some dictionaries avoid including idioms used only in slang or perceived as vulgar or obscene (e.g., Molotkov, 1986; Petermann *et al.*, 1995), others try to represent current usage in all stylistic registers (e.g., Baranov and Dobrovol'skij, forthcoming). There are also special dictionaries which focus on idioms with vulgar and obscene constituents, aiming to fill the gap that is typical of traditional academic dictionaries (e.g., Bui, 1995).

Often the lexicographers' decisions about what to include in a dictionary and what to leave out depend on the potential users. For example, Lubensky (1995) is aimed primarily at English-speaking learners of

Russian. The inventory of head phrases in this dictionary is largely determined by this orientation.

Idiom Semantics and Pragmatics as a Lexicographic Issue

In this section, the focus is on the specifics of idiom semantics and pragmatics. If an idiom is explained via a corresponding near-synonymous word it remains unclear what the difference is between the idiom and that word. From a practical point of view, this method of idiom representation is acceptable if the dictionary is aimed at speech perception rather than speech production. The aim of an active dictionary of idioms is to demonstrate the specific features of idiom use in discourse. There are various different, ways to achieve this goal. Some of them will be briefly discussed here.

Not only theoretically grounded idiom research but also practical lexicography needs to go into detail when describing the meaning of idioms. This can be demonstrated with the help of the following example. Consider idioms (1) and (2).

(1) German *den Bock zum Gärtner machen*
'to make the ram/he-goat into the gardener'
'to allow a person, who seems likely to do harm in a given field of activities, to do just these things'

(2) Russian *puskat' kozla v ogorod*
'to let the he-goat into the kitchen garden'
'to allow a person, who seems likely to do harm in a given field of activities and to derive benefit for himself/herself, to do just these things'

Idioms (1) and (2) are very similar with regard to both their meanings and their lexical structure. So, it is understandable why all German-Russian and Russian-German dictionaries treat them as full equivalents. Nevertheless, these idioms show subtle semantic differences, which have to be taken into account while compiling an active dictionary of idioms. The semantic interpretations of (1) and (2) differ with regard to the semantic element 'to derive benefit for himself/herself,' which is part of the meaning of the Russian idiom (2) but not of the German idiom (1). Semantic differences such as these are of prime importance for bilingual lexicography. The lack of research findings in this area is responsible for the fact that so far no one has compiled a bilingual dictionary of idioms which pays enough attention to the semantic differences between nearly equivalent idioms. See for more detail Dobrovol'skij (2000).

It does not mean, of course, that there are no idiom dictionaries with good semantic explications. Compare, *inter alia*, dictionaries such as Cowie *et al.* (1993), Lubensky (1995), Moon (1995), Longman (1998), Speake (1999), Spears (1999), and Lurati (2001), which, in most cases, explain and define idioms very exactly. See also the semantic definition of (2) from Lubensky (1995): "to allow s.o. access to some place where he may be esp. harmful or to something that he wants to use or exploit for personal gain."

Semantic definition is not the only way to explain the meaning of an idiom. The ordering of head phrases can itself have an explanatory function. Compare onomasiological dictionaries (thesauri) such as Schemann (1989), Galisson (1984), Duneton and Claval (1990), Spears (2000), Bárdosi (2003), and Baranov and Dobrovol'skij (forthcoming). In an idioms thesaurus the entries are grouped not alphabetically, but according to their semantic fields (for details see Dobrovol'skij, 1995).

In bilingual dictionaries the means of explaining the meaning is not primarily the semantic definition but a set of equivalents from the target language. But since similar idioms in the source and target languages, in most cases, do not coincide in all their relevant features (cf. examples [1] and [2]), additional means of semantic explanation are also needed. These can be both semantic definitions and usage notes provided in addition to equivalents. A very convincing example of this technique is found in Lubensky (1995).

Since for adequate usage of idioms it is necessary to have knowledge not only about their semantics but also about their pragmatics, the entry structure has to include a special section for pragmatic information. This kind of information can be presented either in the form of usage notes or in the form of usage labels. For example, explaining the meaning of the idiom *kick the bucket*, Moon (1995) included the note "used to refer to someone's death in a light-hearted or humorous way," whereas Cowie *et al.* (1993) used the label 'informal' (example from Hanks, 2000).

Some dictionaries of idioms (occasionally) give etymological information (e.g., Molotkov, 1986; Cowie *et al.*, 1993; Lubensky, 1995; Duden, 2002; Rey and Chantreau, 2003), others do not (e.g., Moon, 1995; Baranov and Dobrovol'skij, forthcoming). Both decisions are acceptable; it depends on the users addressed by a given dictionary. However, what is extremely important with regard to etymology is that this information should not be mixed up with the semantic and pragmatic explanations. Otherwise it may turn out to be misleading by reflecting not the current usage, but the origin of a given idiom.

Last but not least, an idiom dictionary (at least, an active one) has to include illustrative material. Here

idiom dictionaries show a range of possibilities: from brief invented examples to rich literary citations. In bilingual dictionaries, illustrations can be translated by the lexicographers themselves or (in case of literary citations) they can be presented along with their published translations.

Concluding Remarks

Idiom dictionaries benefit from the rapid development of large text corpora. Corpora help not only to quickly find more and better authentic examples, but also to adequately divide the semantic structure of a given idiom into different readings, describe its syntactic behavior, and provide acceptable semantic definitions and usage labels. However, corpora alone cannot solve the problems of appropriate lexicographic representation of idioms. What is also needed, to no lesser extent, is a sound theoretical background, a clear understanding of the relevant linguistic specifics of idioms.

Idioms

J Ayto, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The term *idiom* may be defined as an institutionalized multiword construction, the meaning of which cannot be fully deduced from the meaning of its constituent words, and which may be regarded as a self-contained lexical item. For example, in Modern English the expression *haul over the coals* makes little sense if each word is interpreted separately and literally; it has to be decoded as a single semantic unit: 'to admonish severely.'

Beneath this broad definition are grouped a large number of different constructions that inhabit intersecting spectra of semantic opacity, compositional fixity, and syntactic function.

Semantic Opacity

At one extreme are phrases in which each word defies literal understanding: *cut the mustard* 'to come up to the expected standard', *eat crow* 'to admit humiliatingly that one was wrong', *kick the bucket* 'to die'. Such idioms may contain fossilized words that have no independent existence in Modern English: for example *pig in a poke* 'a purchase which turns out not to be what the vendor claimed', where *poke* is an old word for a bag or sack.

Some fixed phrases may contain elements used in their literal sense. In *get down to brass tacks* 'to start frankly discussing the essentials of a matter', for instance, *get down to* is broadly speaking being used as it would be in a (small) range of other collocations (for example, *get down to business*). Such elements may be variable (for example, *know the ropes, show someone the ropes*, where *the ropes* are 'the special methods or procedures').

In some cases, all the main word elements have their literal meaning, and it is only the particular combination in which they appear that confers a meaning beyond the sum of the parts: *bread and butter*, for example, is 'bread spread with butter' (as a fully metaphoricized idiom it can also mean 'a source of income').

Many fixed phrases have a meaning that could not be described as literal (perhaps because their genesis was obviously metaphorical, or because they preserve a usage no longer current in the language) but which nevertheless yield fairly readily to interpretation: *behind the times* 'old-fashioned', *daylight robbery* 'a sale at an extortionate price', *the talk of the town* 'a subject widely discussed or gossiped about'.

At the other extreme of the meaning spectrum are institutionalized phrases that are completely semantically transparent: *beneath contempt, from bad to worse, go wrong*. Within this category come many clichés and also so-called 'freezes' (Fenk-Oczlon, 1989), in which pairs of words are fixed in a particular order (*knives and forks, friends and neighbors*). Their compositional fixity allies them with idioms, but most linguists would exclude them from full membership of the category because of their semantic transparency.

Combinations of this sort shade into collocations, in which the choice of words to express another word's lexical or grammatical relationships is severely restricted (*afraid of, arrive at/come to/reach a decision*).

The closer to the opaque end of the spectrum a multiword construction is, the more likely it is to be regarded as a fully fledged idiom, but assignment to a particular category may depend on the delicacy of judgment applied to the semantics of a particular combination. As we have seen, *bread and butter*, which from a formal point of view is a freeze, is more than the sum of its semantic parts; and some might claim that the same is true of, for example, *knives and forks*, the combination of which narrows down the interpretation of its constituents to eating implements.

Many compound nouns satisfy the criteria of semantic opacity applied above. For instance, the semantic force of *green* in *green room* 'room for performers when not on stage' is not readily deducible (it probably comes originally from the painting of the room green to rest the artists' eyes after the glare of the limelight). However, such compounds are generally not regarded as idioms unless the complete lexical item is metaphoricized, for example, *blue blood* 'noble or royal

The term *idiom* may be defined as an institutionalized multiword construction, the meaning of which cannot be fully deduced from the meaning of its constituent words, and which may be regarded as a self-contained lexical item. For example, in Modern English the expression *haul over the coals* makes little sense if each word is interpreted separately and literally; it has to be decoded as a single semantic unit: 'to admonish severely.'

Beneath this broad definition are grouped a large number of different constructions that inhabit intersecting spectra of semantic opacity, compositional fixity, and syntactic function.

Semantic Opacity

At one extreme are phrases in which each word defies literal understanding: *cut the mustard* 'to come up to the expected standard', *eat crow* 'to admit humiliatingly that one was wrong', *kick the bucket* 'to die'. Such idioms may contain fossilized words that have no independent existence in Modern English: for example *pig in a poke* 'a purchase which turns out not to be what the vendor claimed', where *poke* is an old word for a bag or sack.

Some fixed phrases may contain elements used in their literal sense. In *get down to brass tacks* 'to start frankly discussing the essentials of a matter', for instance, *get down to* is broadly speaking being used as it would be in a (small) range of other collocations (for example, *get down to business*). Such elements may be variable (for example, *know the ropes, show someone the ropes*, where *the ropes* are 'the special methods or procedures').

In some cases, all the main word elements have their literal meaning, and it is only the particular combination in which they appear that confers a meaning beyond the sum of the parts: *bread and butter*, for example, is 'bread spread with butter' (as a fully metaphoricized idiom it can also mean 'a source of income').

Many fixed phrases have a meaning that could not be described as literal (perhaps because their genesis was obviously metaphorical, or because they preserve a usage no longer current in the language) but which nevertheless yield fairly readily to interpretation: *behind the times* 'old-fashioned', *daylight robbery* 'a sale at an extortionate price', *the talk of the town* 'a subject widely discussed or gossiped about'.

At the other extreme of the meaning spectrum are institutionalized phrases that are completely semantically transparent: *beneath contempt, from bad to worse, go wrong*. Within this category come many clichés and also so-called 'freezes' (Fenk-Oczlon, 1989), in which pairs of words are fixed in a particular order (*knives and forks, friends and neighbors*). Their compositional fixity allies them with idioms, but most linguists would exclude them from full membership of the category because of their semantic transparency.

Combinations of this sort shade into collocations, in which the choice of words to express another word's lexical or grammatical relationships is severely restricted (*afraid of, arrive at/come to/reach a decision*).

The closer to the opaque end of the spectrum a multiword construction is, the more likely it is to be regarded as a fully fledged idiom, but assignment to a particular category may depend on the delicacy of judgment applied to the semantics of a particular combination. As we have seen, *bread and butter*, which from a formal point of view is a freeze, is more than the sum of its semantic parts; and some might claim that the same is true of, for example, *knives and forks*, the combination of which narrows down the interpretation of its constituents to eating implements.

Many compound nouns satisfy the criteria of semantic opacity applied above. For instance, the semantic force of *green* in *green room* 'room for performers when not on stage' is not readily deducible (it probably comes originally from the painting of the room green to rest the artists' eyes after the glare of the limelight). However, such compounds are generally not regarded as idioms unless the complete lexical item is metaphoricized, for example, *blue blood* 'noble or royal

ancestry', *dark horse* 'a secretive or little-known person who does something unexpectedly remarkable,' *knight in shining armor* 'someone who comes bravely to the rescue'. The referent of *green room* is literally a type of room, so the term does not qualify as an idiom.

Grammatical and Compositional Fixity

Most idioms that function as verbs or nouns participate in the inflectional variations normal for their word-class: verbs, for example, can be marked by a particular person or tense (*She has let the cat out of the bag*), and nouns can be pluralized (*bears with sore heads*). Beyond this, however, many idioms are subject to a range of grammatical restrictions, and are capable to a greater or less degree of being altered or added to or having their word order changed.

The most firmly fixed verbal idioms resist passivization and other standard transformations: *Fred kicked the bucket* (= died) is well-formed; **The bucket was kicked by Fred* and **It was the bucket that Fred kicked* are not. Others are not so restricted syntactically: *I'm used to having my leg pulled* (= being teased) is no less acceptable than *You're pulling my leg!*

Fixed idioms do not allow insertions or alterations: **call it another day* would not be an acceptable variation on *call it a day* 'to finish what one is doing'. On the other hand, *leave no stone unturned* 'to make every possible effort' could legitimately be expanded to *leave no legal stone unturned*, and *You can't keep a good man down* could be recast as, for example, *You can't keep a good politician down*. *Kick the bucket* cannot become **kick the pail*, nor (except in language play) can *spill the beans* 'to reveal secrets' be **spill your beans*, but *Your eyes are bigger than your stomach/tummy/belly* are all equally acceptable.

Transitive verbal idioms may have a vacant slot for a direct object (*sweep* (someone) *off their feet* 'to overwhelm someone suddenly by inspiring a strong emotion of love within them for you'), an indirect object (*give* (someone) *a piece of one's mind* 'to scold someone angrily'), or a prepositional object (*clap eyes on* (someone) 'to see someone').

At the most 'fluid' end of the spectrum are constructions such as *what is X doing Y?*, seeking elucidation of an incongruous situation (as in *What's that muddy boot doing on the table?*) and V + obj + *away*, denoting the using up of time by a particular activity (as in *They danced the night away*) (Kay and Fillmore, 1999; Jackendoff, 1997). In idioms of this sort, the overall meaning appears to be determined more by the syntactic structure than by any semantic properties of the fixed elements, and they have been termed 'constructional idioms'. (Idioms of this sort, midway between completely fixed idioms, which have to be interpreted as indivisible units, and ordinary non-idiomatic combinations, which are interpreted according to fully productive grammatical rules, require a new type of grammar to elucidate them. An approach termed 'construction grammar' (Kay and Fillmore, 1999; Jackendoff, 2002: 181) has been proposed, which deploys a set of extra, bolt-on rules, beyond the general grammar of the language, to deal with these semi-idioms.)

Established norms of fixity are always liable to be set aside by creative language users. Once the basic models are in existence, it is perfectly feasible that such utterances could be produced as 'There'll be no *bucket-kicking* (= dying) around here yet' (violating syntactic fixity) or 'Never *darken* my *patio* again' (perhaps said to an unwelcome barbecue guest; replacing the expected *door* with *patio* and thus violating compositional fixity).

A related but subconscious phenomenon is the splicing of two or more idioms together, as in *count your lucky stars*, combining *count one's blessings* and *thank one's lucky stars*, both invoking gratitude for good fortune, and *Don't burn your bridges until you've come to them*, combining *burn one's bridges* 'to take an irrevocable step' with *cross one's bridges before one has come to them* 'to act prematurely'. The resulting blend (often superficially plausible, but, if not involving nearly synonymous idioms, semantically incongruous when more closely examined) is related to the 'mixed metaphor' problem.

Diachronically, idioms are no more fixed than any other element of the lexicon. Constituent words may change over time (*have something at one's fingers' ends* 'to be very familiar with or skilled at something' has largely been replaced in Modern English by *have something at one's fingertips*). And semantic change, which is inherent in the initial process of metaphoricization (*jump the gun* 'to anticipate the starting pistol in a race' > 'to act precipitately'), may continue to operate: *beg the question*, for instance, originally meant 'to assume something is true without showing any proof', but it is now frequently used for 'to avoid giving a direct answer to a question' and also for 'to seem to invite an obvious question'.

Syntactic Function

Idioms occupy a wide range of syntactic roles, from membership in individual word classes to predicates and entire sentences.

Verbs

Idiomatic verb phrases function syntactically as verbs in a sentence. Their internal structure is commonly V + O, with or without further elements: *change hands* 'to be exchanged', *stick one's neck out* 'to take a great risk', *clap eyes on* 'to see', *make heavy weather of* 'to perform (a task) too laboriously', *rattle* (someone's) *cage* 'to agitate someone'. Idiomatic combinations of verb + particle (phrasal verbs) are usually categorized as idioms, too: *shut up* 'to stop speaking', *take in* 'to deceive', *back down* 'to resile from a previous position', *play away* 'to have an extramarital sexual relationship', *root for* 'to support enthusiastically', *put up with* 'to tolerate'. Combinations with other adverbials are also frequent: *go* (someone's) *way* 'to behave in the way someone wants', *cut both ways* 'to have an equal effect on both parties', *go west* 'to die or be broken', *live in sin* 'to cohabit sexually when not married'. Other fairly frequent patterns are a verb with the dummy object *it*: *lump it* 'to put up with a disagreeable state of affairs'; and combinations of two or more verbs with a conjunctive: *pick and choose* 'to be excessively selective'.

Verbal idioms can frequently function as the entire predicate of a sentence: [*He*] *threw in the towel* (= gave up); [*The bridge*] *blew up* (= was destroyed by explosion).

Nouns

Nominal idioms may be formed by either premodification of a noun: *the hot seat* 'a position of uncomfortable difficulties', *salad days* 'time of youthful inexperience', *monkey business* 'dishonest or suspicious activities', *the bum's rush* 'abrupt ejection or dismissal'; or postmodification: *fish out of water* 'someone in an uncomfortably unfamiliar or inappropriate situation', *salt of the earth* 'someone very honest, dependable, etc.', *manna from heaven* 'an unexpected source of relief'; or by conjunction of two or more nouns: *sackcloth and ashes* 'extreme contrition', someone's *pride and joy* 'someone or something regarded with particular affection and pride', *meat and drink* 'a main source of pleasure, encouragement, etc.', *any Tom, Dick, or Harry* 'any unspecified ordinary person'.

A high proportion of nominal idioms are evaluative, quasi-adjectival, and as such generally appear as predicates: 'Tom was a real *tower of strength* (= was very supportive) through those difficult times.' 'That exam was a *piece of cake.*' (= was very easy).

Adjectives

Adjectival idioms may be formed by premodification of an adjective: *brand new* 'completely new', *dirt poor* 'extremely poor'; by postmodification: *dyed-in-the-wool* 'inveterate', *holier-than-thou* 'sanctimonious', *wet behind the ears* 'inexperienced'; and by conjunction: *hot and bothered* 'excited and annoyed', *tired and emotional* 'drunk', *spick and span* 'very clean and tidy', *footloose and fancy-free* 'free from entanglements (mainly physical freedom)'. Similes, which function adjectivally, can be categorized with idioms if their meaning is not transparent: *bright as a button* 'lively and clever', *crazy like a fox* 'astute'.

Adjectival idioms based on prepositional phrases are by their nature usually found in predicates: 'I'm feeling rather *under the weather'* (= unwell), 'They're *in cahoots'* (= collaborating), 'You're *out of your mind'* (= insane), 'He's *over the hill'* (= past his best age); but prenominal use is not ruled out: 'an *in-your-face* (= confrontational) attitude', 'an *out-of-touch* (= unaware of current developments) prime minister'.

Adverbs

Many adverbial idioms are compositionally similar to adjectival idioms: *by and large* 'generally speaking', *on and off* 'irregularly', *once or twice* 'a few times', *by the skin of one's teeth* 'by a very narrow margin', *from A to Z* 'completely, from beginning to end', *on paper* 'theoretically'. Other types occur, though: *all along* 'from the beginning', *ever so* 'extremely', *no end* 'greatly'.

Others

Idioms can also function as prepositions (*in view of* 'after taking (something) into consideration', *by dint of* 'by means of', *to the tune of* 'in the amount of', *over and above* 'in addition to') and conjunctives (*not to mention* 'and also', *as long as* 'on condition that').

Idioms can also constitute complete utterances or sentences: (*Well,*) *I never* 'I am surprised'. Many are jussive: *Never mind* 'Do not concern yourself', *God forbid* 'I hope that will not happen'; or are used interjectionally: *Big deal!* (used to disparage an exaggerated claim), *Not on your life!* 'Certainly not!', *So there!* (used as a verbal riposte). Standardized (or clichéd) sayings (*Great minds think alike*, *There's one born every minute*) merge into fully-fledged proverbs (*Many hands make light work*). More-or-less buried literary allusions (*There's the rub* – identifying a drawback; originally from Shakespeare's *Hamlet*) make a significant contribution to idioms of this sort.

Clichés

The term *cliché* implies a value judgment, of overuse and consequent staleness. It denotes an institutionalized expression, of greater or less semantic

transparency, which has been heard and seen so often that it strikes one as annoyingly hackneyed, and condemns its user as unoriginal. Membership of the category is adjudicated subjectively, and so will differ from person to person, but there are usually several high-profile phrases in circulation that most people would agree to stigmatize: for example, *at the end of the day* 'when everything has been taken into consideration', *the name of the game* 'the main idea or intention', *in this day and age* 'now'. The desirability of originality is a comparatively recent phenomenon: before the 19th century, the use of stock expressions was not seen as worthy of condemnation, and *cliché* in its present-day usage is not recorded in English before the 1890s.

Ihre, Johan (1707–1780)

K-Å Forsgren, Umeå Universitet, Umeå, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Johan Ihre was a Swedish historian, comparative linguist, dialectologist, and runologist who was born in Lund in 1707 and died in Uppsala in 1780.

At the age of 10 Ihre moved to Linköping and in 1720, after the death of his father, who had been a professor of theology in Lund and then dean in Linköping, moved to Uppsala. In Uppsala he took up studies of theology, history, and classical and modern languages, among other subjects, and graduated in 1728. From 1730 to 1733 he traveled around Europe and received his doctor's degree in 1731. In 1735 he was appointed professor of Latin poetry and in 1738 professor of the Skyttean chair of Politics and Eloquence, where he gave lectures on European history and politics. At the same time he also gave lectures on the Swedish language, which led to extensive comparative and historical studies. Ihre was outspoken in theological and political matters, which led to conflicts; he was also heavily fined in a trial (1750). He refrained from such activities thereafter and devoted himself entirely to his scholarly work.

The Silver Bible, *Codex argenteus*, at the university library of Uppsala caught his interest, and together with his assistant Erik Sotberg he revised and considerably improved earlier editions (*Ulphilas illustratus*, 1752, 1755) and published a great number of other dissertations, 450 altogether. In 1766 the first dictionary of Swedish dialects, *Swenskt dialectlexicon*, appeared and in 1769, the first Swedish etymological dictionary, *Glossarium Suiogothicum*. The latter took no less than 30 years to complete and must be regarded as one of Ihre's most important achievements. Its aim was to determine the position of Swedish in relation to other European languages. Three works on the history of the runes were published as dissertations: *De runarum in Svecia antiquitate* (1769), *De runarum patria et origine* (1770), and *De runarum in Svecia occasu* (1771–1773). A dictionary, *Lexicon runarum*, was never finished.

Ihre is generally regarded as Sweden's most outstanding linguist, nationally and internationally highly esteemed by his contemporaries. Ihre was a very good, entertaining, and popular lecturer, taking a vivid interest in his students. The value and originality of his results were questioned, e.g., by Rasmus Rask, and still are today (Hovdhaugen *et al.*, 2000: 119–121). There is no doubt, however, that he, particularly in his *Glossarium Suiogothicum*, was a forerunner and pioneer of comparative and historical linguistics of the early 19th century, basically arriving

transparency, which has been heard and seen so often that it strikes one as annoyingly hackneyed, and condemns its user as unoriginal. Membership of the category is adjudicated subjectively, and so will differ from person to person, but there are usually several high-profile phrases in circulation that most people would agree to stigmatize: for example, *at the end of the day* 'when everything has been taken into consideration', *the name of the game* 'the main idea or intention', *in this day and age* 'now'. The desirability of originality is a comparatively recent phenomenon: before the 19th century, the use of stock expressions was not seen as worthy of condemnation, and *cliché* in its present-day usage is not recorded in English before the 1890s.

The value and originality of his results were questioned, e.g., by Rasmus Rask, and still are today (Hovdhaugen *et al.*, 2000: 119–121). There is no doubt, however, that he, particularly in his *Glossarium Suiogothicum*, was a forerunner and pioneer of comparative and historical linguistics of the early 19th century, basically arriving

at the conclusion that all European languages except Sámi, Finnish, and Hungarian were of the same origin. His method was empirical, concentric, and diachronic: using the Swedish of his time as a point of departure he proceeded to the oldest text sources, such as the Edda, the Bible, and the runes. In his further comparative studies of Gothic and old Germanic, Celtic, and Roman languages and, further, Greek, Latin, and even Persian, he also used dictionaries. The corpus is still useful today. Ihre was thus a good representative of the Enlightenment and his studies put an end to the hyper-patriotic etymological speculations, e.g., of father and son Olav Rudbeck.

Ilocano

C Rubino, Rockville, MD, USA

© 2006 Elsevier Ltd. All rights reserved.

Ilocano (Iloko, Ilokano, Samtoy) is an Austronesian language with 8 million speakers whose ancestral homeland is northwest Luzon Island, Philippines. It is the third largest language in the Philippines after Tagalog (the basis of the Philippine national language) and Cebuano (Sugbuhanon). Ilocano is the largest member of the Cordilleran language family of Northern Philippine languages. Within the family, Ilocano forms its own branch with no close relatives. Other Cordilleran languages include: the Alta branch, the South Cordilleran languages of Kallahan, Ibaloi, Pangasinan, and Ilongot; the Central Cordilleran languages of Isinai, Ifugao, Balangao, Bontok (Bontoc), Kankanay (Kankanaey), Kalinga, and Itneg; Arta; and the Northern Cordilleran languages that can be subdivided into the Cagayan Valley languages of Gaddang, Itawis (Itawit), Agta, Ibanag, Atta, Yogad, and Isneg (Isnag), and the North East Luzon branch that comprises Paranan and the Dumagat (Agta, Casiguran Dumagat) languages.

The original Ilocano provinces include Ilocos Norte, Ilocos Sur, and La Union, but Ilocanos have migrated extensively and even predominate in many localities in the neighboring provinces of Abra, Pangasinan, Tarlac, Benguet, and Cagayan. In the provinces of Abra and Pangasinan, many of the Ilocano speakers are ethnically Tinguian or Pangasinan, respectively, who have traded in their native tongues for the more prestigious *lingua franca*. There are also large communities of Ilocano speakers in the major urban centers of the United States, most notably in California and Hawaii.

Unlike most of the major languages of the Philippines, dialectal variation in Ilocano is minimal. There are two main dialects, Northern and Southern, easily distinguishable by slight lexical differences, intonation patterns, and the pronunciation of the native phoneme /e/, which is pronounced as the *e* in English *let* in the Northern dialects of Ilocos Norte and parts of Ilocos Sur, and as a high, central-back unrounded vowel [ɯ] in Abra, the southern parts of Ilocos Sur, La Union, Tarlac, and Pangasinan.

Ilocano has 15 native consonantal phonemes, and a glottal fricative used in one native word in the southern dialect, *haán* 'no', the colloquial variant of *saán*, as well foreign loans (see **Table 1**). Of the consonants, 14 (all but the glottal stop) may appear geminate in roots; the glottal stop only occurs geminate across morpheme boundaries: *agaC-árak* [agaʔʔá:rak] 'smelling of alcohol'.

Stops are unaspirated and, in final position, unreleased. The voiceless velar stop is pronounced quite

at the conclusion that all European languages except Sámi, Finnish, and Hungarian were of the same origin. Ilocano (Iloko, Ilokano, Samtoy) is an Austronesian language with 8 million speakers whose ancestral homeland is northwest Luzon Island, Philippines. It is the third largest language in the Philippines after Tagalog (the basis of the Philippine national language) and Cebuano (Sugbuhanon). Ilocano is the largest member of the Cordilleran language family of Northern Philippine languages. Within the family, Ilocano forms its own branch with no close relatives. Other Cordilleran languages include: the Alta branch, the South Cordilleran languages of Kallahan, Ibaloi, Pangasinan, and Ilongot; the Central Cordilleran languages of Isinai, Ifugao, Balangao, Bontok (Bontoc), Kankanay (Kankanaey), Kalinga, and Itneg; Arta; and the Northern Cordilleran languages that can be subdivided into the Cagayan Valley languages of Gaddang, Itawis (Itawit), Agta, Ibanag, Atta, Yogad, and Isneg (Isnag), and the North East Luzon branch that comprises Paranan and the Dumagat (Agta, Casiguran Dumagat) languages.

The original Ilocano provinces include Ilocos Norte, Ilocos Sur, and La Union, but Ilocanos have migrated extensively and even predominate in many localities in the neighboring provinces of Abra, Pangasinan, Tarlac, Benguet, and Cagayan. In the provinces of Abra and Pangasinan, many of the Ilocano speakers are ethnically Tinguian or Pangasinan, respectively, who have traded in their native tongues for the more prestigious *lingua franca*. There are also large communities of Ilocano speakers in the major urban centers of the United States, most notably in California and Hawaii.

Unlike most of the major languages of the Philippines, dialectal variation in Ilocano is minimal. There are two main dialects, Northern and Southern, easily distinguishable by slight lexical differences, intonation patterns, and the pronunciation of the native phoneme /e/, which is pronounced as the *e* in English *let* in the Northern dialects of Ilocos Norte and parts of Ilocos Sur, and as a high, central-back unrounded vowel [ɯ] in Abra, the southern parts of Ilocos Sur, La Union, Tarlac, and Pangasinan.

Ilocano has 15 native consonantal phonemes, and a glottal fricative used in one native word in the southern dialect, *haán* 'no', the colloquial variant of *saán*, as well foreign loans (see Table 1). Of the consonants, 14 (all but the glottal stop) may appear geminate in roots; the glottal stop only occurs geminate across morpheme boundaries: *agaC-árak* [agaʔʔá:rak] 'smelling of alcohol'.

Stops are unaspirated and, in final position, unreleased. The voiceless velar stop is pronounced quite

Mid	(ɛ)			(o)
Low		a		

far back and fricates before vowels. Unlike in Tagalog, glottal stop does not phonemically appear word-finally. Glottal stop is not represented orthographically word-initially, and word-medially, it is represented with a hyphen. Syllables have mandatory onsets, so the basic syllable structure of the language is CV(C): *ába* 'taro' [ʔá:.ba].

The phonemes /t/, /d/, and /s/ palatalize to [tʃ], [dʒ], and [ʃ] before the palatal glide /y/ or its equivalent (i + vowel), e.g., *siák* 'I' [ʃak], *tián* 'belly' [tʃan], *idiáy* 'there' [idʒay]. Because of many borrowings from English, Spanish, and colloquial Tagalog where these palatal sounds are not complex phoneme sequences, the phonemic status of [tʃ], [dʒ], and [ʃ] is open to debate.

Ilocano has four native vowel phonemes /i, e, a, and u/. The new phonemes /o/ and /ɛ/ are post-Hispanic (only in loanwords) (cf. Table 2). In the northern dialects, the phoneme /e/ is pronounced as /ɛ/, not differentiated from its pronunciation in Spanish loanwords.

The high vowel [u] is lowered considerably in word-final syllables, and is thus usually represented in the orthography, e.g., *ások* 'my dog' /á:su = k/.

Sequences of two vowels other than the diphthongs /ia/, /io/, and /ua/ are pronounced as two syllables, with an intervening glottal stop in careful speech, *saán* [sa.ʔan] 'no' but: *al-aliá* 'ghost' [ʔal.ʔal.ya].

Stress is phonemic, e.g., *siká* 'you, familiar' vs. *síka* 'dysentery'. There, are, however, certain environments that attract stress. Stress falls on the last syllable if the penultimate syllable is closed: *paltóg* 'gun', *takkí* 'excrement', *tig-áb* 'belch', *pugtó* 'guess'. Exceptions to this rule include words of foreign origin or words with a velar nasal coda preceding a final syllable: *bibíngka* 'rice cake', *karámba* 'jar' (Spanish loan). In native words, stress also falls on the last syllable if the last vowel is preceded by a consonant and glide: *sarunuén* 'follow', *aniá* 'what'.

Orthographic double vowels following two consonants usually take stress on the first vowel, with an intervening glottal stop or syllable boundary, e.g., *kanabraang* [ka.nab.rá:.ʔang] 'gong', *kulláaw* [kul. lá:.ʔaw] 'owl'. Words that include two identical CVC sequences separated by a vowel usually will carry the stress on the vowel separating them: *salísal* 'compete', *batíbat* 'nightmare'. There are, however, a few exceptions: *yakayák* 'sieve', and *pidipíd* 'closely set together'.

Vowels before geminate consonants and in stressed open (CV) syllables are automatically lengthened: *sála* 'dance' [sá:.la], *babbai* 'girls' [bà:b.bá:.ʔi]. Open reduplicated syllables in roots that contain a vowel sequence also bear secondary stress/lengthening: *na.ka-bà:-ba.ín* 'shameful'.

Like its sister Philippine languages, Ilocano is a head-marking, predicate-initial language. When two nominals appear postpredicately, the agent normally precedes the patient: *P{in}artí ti baró ti kaldíng* (slaughter{PERF.TRANS} ART bachelor ART goat) 'The bachelor slaughtered the goat'. The initial position in Ilocano syntax is reserved for the predicate so constituents in this position are predicative: *Tabbéd ni Bong*. 'Bong is stupid', *alutiít* '(it is a) house lizard'. When a noun phrase does precede a predicate for pragmatic reasons, it is preceded by a pause or the predicate marking particle *ket*. The phrase *Napintas ni Alessandra* 'Alessandra is pretty' can appear inverted as: *Ni Alessandra … napintas* or *Ni Alessandra ket napintas*.

Most syntactic structures follow a head + modifier pattern. Genitives follow their nouns > *ti uken-ko* 'my puppy', *ti uken ni Rafael* 'Rafael's puppy'.

	Non-personal, singular	*Non-personal, plural*	*Personal, singular*	*Personal, plural*
Core	*ti* (neutral), *diay* (definite)	*dagití*	*ni*	*da*
Oblique	*ití*	*kadagití*	*kenní*	*kadá*

Typical of the native languages of the Philippine archipelago, there is a rigid voice distinction in the verbs whereby the semantic relationship between the verb and the pivot (the syntactically most privileged absolutive argument) is signaled by the verb's derivational morphology (Rubino, 2000).

The various voices in Ilocano are shown in Table 3. Each affix has an infinitival/imperative form and a perfective form. Initial CVC reduplication of the verb is employed for progressive (continual) verbs. So the actor voice verb *agdigos* 'take a bath' inflects as *agdigos* 'take a bath', *nagdigos* 'took a bath', *agdigdigos* 'is taking a bath', *nagdigdigos* 'was taking a bath.' The enclitic *=(n)to* which is realized as *=nto* after vowels and *=to* after consonants denotes future time, e.g., *agdigosto* 'will take a bath', *agdigoskanto* 'you will take a bath'. Other derivational possibilities with the root *digos* include *agindidigos* 'pretend to bathe', *pagdígos* 'used for bathing', *kadigos* 'bathing mate', *panagdigos* 'bathing', *idigos* 'to bathe with (+instrument), *agpadigos* 'have a bath', *padigosen* 'bathe someone else', *pagdigusan* 'bathing place', etc.

Ilocano also has a potentive mode used for actions that are abilitative, coincidental, involuntary, or accidental. Potentive verbs are formed with the prefixes *ma-ka-* or *na-ka*, e.g., *na-dungparko ti lugan* 'I accidentally hit the car' vs. *D{in}ungparko ti lugan* 'I hit the car (on purpose)'.

Compared to many other Philippine languages, the Ilocano noun marking system is rather simple, with only two case distinctions, a core case (for the two arguments that appear with a transitive verb or the one argument that appears with an intransitive predicate) and an oblique case for other referents. As is shown in Table 4, plurality in nouns may be expressed by the article. Most countable nouns may also be pluralized by reduplication, e.g., *lalaki* 'boy' > *lallaki* 'boys', *sabong* 'flower' > *sabsabong* 'flowers', *kailian* 'townmate' > *kakailian* 'townmates'.

Ilocano has six sets of pronouns, which encode eight personal distinctions. There are three first person plural distinctions in the language, dual (you and I), exclusive (we but not you), and inclusive (we and you). The second person plural pronouns may be used to a single address to express politeness.

Independent pronouns are used predicatively (see Table 5). Ergative (genitive) and absolutive pronouns are enclitic; they behave like suffixes that do not attract stress shift, e.g., *Napán-ak idiáy* 'I went there', *sá-ak napán* 'then I went'. Monosyllabic enclitics are usually not immediately segmentable by native speakers and some show allomorphic variation dependent upon phonological environment. After the suffixes *–an* (NOMINALIZER; DIRECTIONAL) and *–en* (PAT), the first and second person ergative enclitics fuse with the final *n* to *–k*, and *–m*, respectively, e.g., *basaek*/ basa-en = k(o)/ 'I'll read it'. The first and second ergative enclitics also lose their final vowel after vowels, e.g., *adi-m* 'your younger brother', unless they follow the monosyllabic adverbs *sa* 'then' or *di* 'negation' or precede the adverbial enclitic *=(e)n* 'now, already' in which they maintain their full forms, e.g., *kuarta-k* 'my money' vs. *kuarta-ko-n* 'It's my money now'.

When two enclitic pronouns meet in Ilocano, they fuse in such a way that some agentive distinctions are neutralized. Thus *gayyem-nak* may mean both 'I am your friend' or 'I am his/her friend'; *Ay-ayaten-da-ka* can mean 'They love you' or 'We love you'.

	Remote	*di*	*daydí*	*dagidí*	*kadaydí*	*kadagidí*

Ilocano deictics include spatial/temporal demonstratives (which have abbreviated article forms) and temporal adverbs that mark relative time. The temporal adverbs are *itá* 'now, today', *itattá* 'right now', *itattáy* 'just a while ago, immediate past', *itáy* 'a while ago, recent past', and *idí* 'a while ago, remote past'. Temporals can mark both verb phrases and temporal nouns: *N-ag-paráng idí*. (PF-ACT-appear REM.PST) 'It appeared a while back', *idí rabií* (REM.PST night) 'last night'. There is also a future marker *(in)ton(o)* that precedes temporal nouns; it cannot be used as a temporal adverb: *intón bigát* (FUTURE morning) 'tomorrow'.

The nontemporal Ilocano demonstratives mark three degrees of spatial orientation and two degrees of temporality (see Table 6).

The recent and remote articles and demonstratives are used for referents that are not visible in the speech event. They mark referents that may be dead, nonactual, or somehow distanced from the speech event. Referents that are recently activated into the consciousness of the speaker may also appear with a nonvisible demonstrative. Compare *N-ag-paráng ni Erning*. 'Erning appeared/showed up' vs. *Nagparáng daydi Erning*. 'The late Erning appeared (as a ghost)'; *Ania ti nágan = mo?* 'What is your name (*nagan*)' vs. *Ania tay náganmo [manén]*? 'What was your name [again], (I used to know it)?'

Imaging and Measurement of the Vocal Tract

Imaging Techniques to Measure the Vocal Tract

The internal structures of the vocal tract are difficult to measure without impinging upon their normal movement patterns. Imaging techniques overcome that difficulty because they measure internal movement without directly contacting the structures. Imaging techniques keep increasing in popularity because of their reduced cost, improved measurement capabilities, and global depiction of the tongue or vocal tract. Three well-known imaging techniques have been applied to speech research: computed tomography (CT), ultrasound, and cine-magnetic resonance imaging (MRI), including tagged cine-MRI (tMRI). Imaging systems provide very different information than do other physiological measures; that is, they provide information about the shape and position of the entire imaged structure rather than a single point on the structure. The imaging techniques described in this article create images in a fundamentally similar way. They construct a tomograph, or an image of a slice of tissue, by projecting a thin, flat beam through the tissue in a single plane.

Four tomographic planes are used in imaging (see Figure 1). They are the sagittal, coronal, oblique, and transverse (axial) planes. The midsagittal plane is a longitudinal slice, from top to bottom, down the median plane, or midline, of the body (dashed line). The parasagittal plane is parallel to the midline of the body but off-center. The coronal plane is also a longitudinal slice. It is perpendicular to the median plane of the body. The oblique plane is inclined between the horizontal and vertical planes. Finally, the transverse plane lies perpendicular to the long axis of the body; in MRI, it is called the transaxial plane, or more commonly, the axial plane.

Computed Tomography (CT)

The first tomographic technique of interest is computed tomography (CT). CT uses X-rays to image slices (sections) of the body. Crosssectional (tomographic) images are made by projecting very thin X-ray beams through a slice of tissue from multiple angles and reconstructing the projections into a single image using a computer. (Encyclopaedia of Medical Imaging, v.1). Figure 2 depicts a CT scanner. The scanner rotates around the body, taking multiple images. The computer composite includes structures that are visible in some scans but obscured in others. Using this technique, tissue slices less than a millimeter thick can be collected rapidly, 15 Hz or faster, and multiple slices (16 or more) can be collected simultaneously. From this multislice dataset, planar sections can be reconstructed in any direction.

The advantage of CT over traditional projection X-rays is its ability to separate objects in the projection direction. X-rays overlay such objects. Thus, a lateral X-ray presents the two sides of the jaw as one, or as multiple shadows. The transverse orientation of the CT displays both sides clearly. Figure 3 shows a

Figure 1 Scan types used in through-transmission and tomographic imaging. There are two X-ray angles contrasted with four tomographic scanning planes.

Figure 2 Schematic of a subject in a CT scanner.

transverse CT of the oropharynx at rest. A vertebral bone appears in the center of the image (white). Just above this, the airway can be seen (black), with the epiglottis and valleculae seen above it. The thyroid cartilage (white) surrounds the airway on three sides. The soft tissue is gray. CT can image soft tissue more clearly than X-rays can because it produces a composite X-ray. By digitally summing a series of scans, the composite section has sharper edges and more distinct tissue definition.

An alternative method of CT data collection is Spiral CT. Spiral CT collects multiple slices at the same time by collecting a single spiral-shaped slice instead of multiple flat planar slices. In the mid 1980s, the cable and drum mechanism for powering the rotation of the machine was replaced with a slip ring. The slip ring allows the CT scanner to rotate continuously, creating a spiral image. Spiral CT scans have very high resolution, but take 20–30 sec to create, and hence are too slow for imaging continuous speech.

Currently the biggest limitation of CT is the radiation exposure. CT is an X-ray. Therefore, only a limited amount of data can be collected on a single subject. In addition, the subject is supine or prone, so gravitational effects on the speech task are different than they are when the subject is upright, and thus some behaviors may not be identical. On the positive side, CT can image the entire tract by sectioning multiple planes for analysis. In addition, the images are extremely clear, and the edges are easy to measure.

Figure 3 CT image of a transverse section of the oropharynx at rest.

The sections are also quite thin (less than 0.5 mm), which allows composite three-dimensional vocal-tract shapes to be constructed by combining multiple sections.

Ultrasound

The most convenient imaging technique is ultrasound. Ultrasound is convenient because the machines are portable, affordable, and easy to use. The ultrasound process is also noninvasive and comfortable for the subject. Ultrasound produces an image by using the reflective properties of sound waves. In the simplest technique, A-mode, a piezoelectric crystal, stimulated by an electric current, emits an ultra high-frequency sound wave. The crystal both emits the sound wave and receives the reflected echo. The sound wave travels through the soft tissue and reflects back when it reaches an interface with tissue of a different density, like bone, or when it reaches air. The best reflections are perpendicular to the beam (see Figure 4, first line). Steeply inclined interfaces refract the sound and may not be visible (second line). Soft tissue typically has an uneven edge (third line). To see a section of tissue, rather than a single point, one needs multiple crystals organized into an array or B-scan transducer. In a B-scan, up to 128 crystals fire sequentially and image a wedge-shaped section of tissue of up to 140 degrees, with the origin at the transducer. Using basic principles of sound conduction, the computer converts the returning echoes into a gray scale video image. The conversion is done by displaying stronger echoes as brighter, whiter edges, and echoes that arrive later in time as being farther away from the transducer.

Figure 5 shows a sagittal image of the tongue. To create such an image, the transducer is placed below the chin and the beam is passed upward through a 1.9 mm-thick section of the tongue. This thin wedge-shaped section is shown in the inserted head picture (see Figure 5). When the sound reaches the air at the surface of the tongue, it reflects back and creates a bright white line. The black area immediately below the line is the tongue body. The border between the white reflection and the black tissue is the surface of the tongue. Interfaces within the tongue may be visible. For example, the genioglossus muscle may be seen in the anterior tongue. Figure 6 depicts the coronal tongue. The smaller crosssectional tongue surface contains a small midsagittal depression. The genioglossus muscle and the muscles of the floor of the mouth appear as black areas. Measurement error on such images is better than 0.7 mm.

The 2-D (two-dimensional) planar image sequences can be visually inspected and analyzed quantitatively.

Figure 4 Schematic of ultrasound reflection patterns emanating from surfaces at different angles to the beam.

Figure 5 Ultrasound image of a sagittal section of the tongue at rest, a schematic of the structures imaged, and a schematic showing the location and direction of the ultrasound beam.

To more clearly visualize tongue motion, it is valuable to view the ultrasound movie as a series of sequential frames. To do this, the contour of the upper tongue surface is extracted using edge detection software (Li *et al.*, 2004) and displayed as a time-motion series (Parthasarathy *et al.*, 2004). Figure 7 shows the time-motion series of midsagittal tongue contours during the word 'golly.'

The viewer is facing the tongue as if looking into the speaker's mouth. The 'surface' is not a 3-D tongue surface. Instead, it is a single midline slice of the tongue that changes shape over time as the word 'golly' is spoken. In this series, color indicates tongue height, with blue representing high and red representing low. The tongue tip is closest to the viewer, and the leftmost frame shows the high back tongue position (blue) expected during the transition from /g/ to /ɑ/. The tongue deforms locally, elevating the tip as it transitions into /l/. The tongue blade elevates for /i/. In addition to visual inspection, the data can be analyzed quantitatively. Multiple repetitions of an utterance can be compared. Calculations, such as the average and standard deviation, can be made for each contour in multiple repetitions of a sequence like 'golly.' Multiple datasets can be compared as well. Two utterances that differ in some way, such as minimal pairs, can be compared quantitatively by calculating global (RMS) and local (segment) differences between each contour of a sequence. [Note that this software is publicly available from the University of Maryland. The Maryland Tongue Analysis Package includes EdgeTrak and Surfaces. EdgeTrak semi-automatically extracts tongue contour edges from a sequence of black and white images, particularly ultrasound. EdgeTrak can also extract and overlay palate contours. Surfaces displays contour sequences

and numerically analyzes them by calculating averages, standard deviations, RMS differences, and local differences.]

Three-dimensional (3-D) or volumetric ultrasound is offered by several companies. Three-dimensional machines typically contain a 2-D transducer that collects a scan in the ordinary way and is then moved mechanically to another location (a few degrees away) to collect the next scan. The internal computer reconstructs the echoes and displays a 3-D volume plus three 2-D planes with multiple slices in each. Frame rates are 24 Hz. There are two drawbacks to 3-D machines, however. First, the data are stored in proprietary format from which 3-D movies or single jpg frames (not a series) can be saved. This makes tongue extraction impractical. Second, there is an enormous amount of data. At 24 fps $\times$ 3 dimensions (sagittal, coronal, transverse) $\times$ 10+ sections in each dimension, the tongue is represented by 720 frames per second. Thus, even if the images could be stored for analysis, their measurement would be slow. In addition, the ultrasound technology is the same as that of 2-D machines, so image quality is not improved and subjects that image badly in two-dimensions also image badly in three-dimensions.

Three-dimensional tongue surfaces, however, can be reconstructed from planar ultrasound data. They can be reconstructed for static phonemes using as few as

Figure 8 Three-dimensional reconstructions of six American–English consonants.

five coronal ultrasound slices of data. Figure 8 shows six American English consonants (Stone and Lundberg, 1996). The tongue tip is at the lower left, and each grid line is 0.5 cm long. Four distinct tongue shapes can be seen: front raising, back raising, complete channel, and two-point displacement.

Similarly 3-D motion can be reconstructed from planar motion. Figure 9 shows a time-motion sequence or 3-D tongue surfaces for the phrase 'it ran a lot.' The reconstructions are based on five coronal and one midsagittal slice.

The vocal folds may be imaged by placing the ultrasound transducer at the front of the neck, at the thyroid notch (Adam's apple), and pointing directly back in the transverse plane (see Figure 10). The vocal folds appear as two gray, wedge-shaped structures in the middle of the image. They are vibrating, but the vibration cannot be seen in a still frame. Instead, the approximating edges of the folds appear as a dark area. The laminae of the thyroid cartilage appear as oblique, divergent white lines just above the folds. The arytenoids appear as bright white dots at the lower margins of the vocal folds. Ultrasound images of the vocal folds reveal abduction and adduction, the existence of tumors, abnormalities, and asymmetries. Real-time videotapes show 'fluttering' of the vocal fold edges. However, the vibration (100 Hz or more) is actually too fast for the ultrasound frame rate (30 Hz), which is why measurement of vocal fold vibration is not practical from ultrasound images.

There are several limitations of ultrasound imaging. The first, which is the inability to see anything but the tongue, can be overcome with certain data collection procedures (Stone *et al.*, 2004). The air at the tongue's surface reflects the sound wave, so that the structures on the far side of the vocal tract, like the palate and pharyngeal wall, cannot be imaged. However, during a swallow, the tongue contacts the palate as the bolus is pushed into the pharynx. During this time, the sound passes beyond the tongue surface to the palate bone and reflects back. Thus, the palate can be measured. If the head and transducer are held steady, the palate can be used as a reference for tongue position. The second disadvantage is the partial obscuration of the tongue extrema by the jaw and hyoid bone. Bone refracts the sound wave, creating an acoustic shadow or dark area obscuring as much as 1 cm of the tongue tip and parts of the tongue root. The tip may be imaged, however, if there is a great deal of saliva in the mouth or if the tongue is low in the mouth.

An advantage of ultrasound is its relatively fast scan rate. The scan rate, typically 30 Hz (some machines collect at 90 Hz), is adequate to image tongue movement for vowels and most consonants, though not fast enough to measure vocal fold

Figure 9 A time-motion display of 3-D tongue surfaces reconstructed from contours collected in the midsagittal and five coronal planes (from Yang and Stone, 2002).

Figure 10 Ultrasound image of the vocal folds in closed (phonation) position.

vibration. A second advantage is that it has no known biological hazards, because the transduction process involves only sound waves. In addition, the real-time, multiple-plane capabilities capture intricate tongue movements and allow reconstruction of the complex three-dimensional deformation of the tongue surface. Finally, the portability of ultrasound machines makes them excellent tools for field work or use in other nonlaboratory data collection environments.

Magnetic Resonance Imaging (MRI)

The third tomographic technique is magnetic resonance imaging (MRI). MRI uses a magnetic field and radio waves rather than X-rays to image a section of tissue. Most MRI machines are 1.5 Tesla, and some machines exert a stronger magnetic field (3 Tesla), which in some cases improves image quality. The software used to run the machine, not the hardware, determines what image types can be acquired. Three types of MRI are used for tissue analysis: tagged Cine-MRI (tMRI), diffusion tensor imaging (DTI), and functional MRI (fMRI). An MRI scanner consists of electromagnets that surround the body and create a magnetic field. MRI scanning detects the presence of hydrogen atoms, which occur in abundance in water and fat. In Figure 11, picture A represents a hydrogen proton spinning about an axis that is oriented randomly. B shows what happens when a magnetic field is introduced. The proton's axis aligns along the direction of the field's poles. Even when aligned, however, the

Figure 11 Artist's rendition of the effects of MRI scanning on hydrogen protons. (After Davis Meltzer, 1987, *National Geographic*. Reproduced with permission.)

Figure 12 Midsagittal MR images of 'i' and 'a.'

proton wobbles, or precesses. In picture C, a short-lived radio frequency (RF) pulse, vibrating at the same frequency as the precession, is introduced. This momentarily knocks the proton out of alignment. D shows the proton realigning, within milliseconds, to the magnetic field. As it realigns, the proton emits a weak radio signal of its own. The emitted radio signals are assembled as a gray scale image in which greater hydrogen density creates whiter tissue. Because the signal emitted by the protons is very weak, many repetitions of the task are collected and the signals summed. The vocal tract appears black, as do the teeth, since neither contain water or fat. Marrow within the bones, which is high in water and fat, and the fat surrounding the head, which is high in hydrogen, are bright white. Figure 12 shows MR images of /a/ and /i/. The tongue, lips, and soft palate are light gray, and their edges are clearly visible.

Of particular interest when measuring the vocal tract is motion. Cine MRI is similar to other cine techniques in that it divides a moving event into a number of still frames. Because the proton emissions from one repetition of an utterance are weak, collecting tongue motion using only one repetition of a task requires a long frame length, and thus summation time is longer (e.g., 4 Hz) or results in fairly poor image resolution. For good resolution of tongue motion and fast frame rates, multiple repetitions are needed, and the 'still frames' from each repetition are summed. This creates a stronger signal for each frame and improved object detail. However, the repetitions must be very precise to prevent blurring. MRI can be collected at fast frame rates, with single or multiple repetitions; more repetitions allow faster frame rates by summing the repeated measures.

Tagged Cine-MRI Tagged Cine-MRI (tMRI) combines Cine-MRI and tissue tagging to identify and track the motion of specific tissue points in a structure such as the tongue. This combination of techniques allows tMRI to image the 'global surface' motions typical of traditional MRI and other imaging techniques as well as the 'local tissue point' motions observed with point-tracking methods, at 15–30 Hz. Tags are a way of marking the tissue prior to collecting

Figure 13 Reference and deformed frames for 'sh' (left) and 'a' (right). The three tag planes capture horizontal, vertical and lateral motion respectively.

the MR image sequence. Tags are created by applying a spatial gradient to the tissue, which demodulates the protons in alternating planes. Demodulation causes the alternating planes of protons to spin out of phase with the rest of the tissue. The demodulated protons are invisible to the machine when the image is read. The invisible proton planes appear as black stripes on the image (see Figure 13). If two orthogonal tag planes are applied, a grid of tags appears (see Figure 14). This magnetic effect is temporarily retained by the tissue (600–1200 ms). Therefore, as the tongue changes shape, the deformation of the invisible proton planes (black) is distinct from the deformation of the visible proton planes, and local tissue motion can be seen (see Figures 13 and 14). Non-cine tagged MRI captures two moments in time. First, a 'reference' state is acquired while the subject holds the tongue steady. The tongue is then moved to a 'deformed' state and a second image is acquired. Shape differences between the reference and deformed tags can be compared (see Figure 13). Tagged Cine-MRI, tMRI, captures continuous motion on multiple frames during the performance of the task (see Figure 14). From the tag deformations, tissue

Figure 14 tMRI frames for 'ka.' The /k/ is in frame 1 and the /a/ in frame 4. The CV motion and local internal tongue deformation can be seen in frames 2 and 3.

points can be tracked and muscle compression calculated during speech.

Diffusion Tensor Imaging Diffusion Tensor Imaging (DTI) was developed in the early 1990s. DTI measures random thermal displacement of water molecules in tissue. DTI has virtually microscopic spatial resolution and images tissue fibers (e.g., muscle) with their orientations. The direction of greatest molecular diffusion parallels the local fiber direction. This is very useful in determining muscle composition, and a fiber map can be drawn and superimposed on a structural image such as an MRI. The fiber map can differentiate among nerve fiber pathways and detail anatomical structures based on their fiber architecture.

Two substantial disadvantages of this technique, however, preclude its use for measuring oropharyngeal structures. First, when fiber directions cross within a single voxel (3-D pixel) the underlying fiber structure is not evident. This situation is typical of oral musculature, especially the tongue, where fiber interdigitation is typical. Second, DTI is sensitive to motion, including respiration. Its use is, therefore, limited to detailing tongue anatomy, not physiology.

Functional MRI Functional MRI (fMRI) of the brain uses the same MR machine as standard MRI, tMRI, and DTI. fMRI is a method of MRI scanning in which tissue contrast is based on blood flow differences, not hydrogen content differences. fMRI detects changes in the neuronal activity of the brain that are blood oxygen level-dependent (BOLD) during the performance of various tasks. In other words, fMRI reflects brain function, not structure. The premise is that spatially distinct, distributed areas of the brain are connected into functional networks organized to produce specific tasks. If these networks can be imaged, they can be mapped geographically to detail brain function during human behavior. Increased neural activity in a region causes increased demand for oxygen, and that oxygen is brought to the region by blood. Replacement of deoxygenated blood with oxygenated blood produces a more uniform magnetic environment, which increases the longevity of the MRI signal. fMRI signals are snapshots that are collected at 10–20 Hz. Multislice recording of the brain and multiple repetitions can be recorded. Some limitations exist in the use of fMRI for speech research. First, the visible effects of the increase in oxygen occur some time after the event itself (0.5 to 8 sec), which results in poor temporal resolution. Second, signals can vary even with no change in brain state. To overcome the latter problem, fMRI usually compares sets of images before and after the task.

As with all instruments, MRI has several drawbacks in general. The first is the time frame. Static MRI and DTI require long periods of immobility for a good image. fMRI has a slow response time. Cine and tMRI require multiple, very precise repetitions. A second drawback is the width of the section. Whereas CT sections are less than 1 mm wide, and ultrasound sections are less than 2 mm, MRI sections are usually 5–10 mm wide. A tomographic scan compresses a three-dimensional volume into two dimensions, which is like displaying a cylinder as a circle. Therefore, in a slice that is 5 mm wide, items that are actually 5 mm apart in the crosssectional plane of the image will appear to be in the same plane. Thus, the hyoid bone and epiglottis might appear in the same transverse slice even though one is several mm below the other. A narrower width on MRI requires a longer exposure time. However, this technology is undergoing improvement, and MRI will undoubtedly require fewer repetitions and use thinner slices in the future.

Final drawbacks for MRI and CT are that the subject must be lying supine or prone, the machine may be unpleasant for some subjects, and use of the machines is costly. A supine or prone position changes the location of gravity with respect to the oral structures and normal agonist/antagonist muscle relationships. Unpleasantness and cost also limit their use when compared to ultrasound. Despite these nontrivial drawbacks, CT images both soft and hard tissue. MRI can image any plane of the body, and tagging allows the tracking of tissue points. Ultrasound provides large quantities of time-motion data

with a single repetition, thin slices, and a noninvasive method. This is more complete movement data on the tongue than can be obtained from any other instrument.

Imaging techniques provide more complete information about vocal tract behavior than are available from direct measures like point-tracking techniques or electropalatography, because imaging techniques measure the inaccessible parts of the tract (e.g., the pharynx), and they measure planes rather than (or in addition to) points. In the future, as their scan rates increase, imaging systems will become more accessible and more widely used. The expanded datasets and multiple perspectives gained from imaged data are transforming the nature of speech science research.

Point-Tracking Measurements of the Vocal Tract

Point-tracking systems measure individual tissue points by affixing pellets to the articulators and tracking their movement during speech. Typically, multiple articulators can be measured at the same time, and tracking speed is fast, so that interarticulator timing measures are quite good. Three point-tracking systems, the electromagnetic articulometer, the X-ray microbeam, and the Optotrak are significantly improving the quality of vocal tract measurements.

Electromagnetic Articulometer (EMA)

The EMA tracks fleshpoint movement by measuring the movement of small receiver coils through alternating magnetic fields. Two such instruments that use roughly similar principles have been developed in Germany (Schonle *et al.,* 1987) and the United States (Perkell *et al.,* 1992). A single 3-D EMA system, which is now being developed and produced, will be introduced here as well (Articulograph AG500, Carstens, Inc., Munich, Germany).

The 2-D Electromagnetic Midsagittal Articulometer (EMMA), (Perkell *et al.,* 1972) A clear plastic assembly, suspended from above, is fit around the subject's head. Three transmitter coils, one above the forehead, one below the chin, and one at the nape of the neck form an equilateral triangle. The transmitter coils each produce an alternating magnetic field that is driven at a different sinusoidal frequency than are the others in order to generate three alternating magnetic fields. The use of three transmitters, and thus three overlapping fields, ensures accuracy in locating the receiver coils, which are placed at midline on vocal tract structures. The receiver coils are small, insulated coils attached with adhesive to articulatory structures at midline. As the alternating magnetic fields pass through the receiver coil, they induce an alternating signal in the receiver coils. The voltage of this signal is inversely related to the distance between the transmitter and the receiver coil. The best resolution in the field space is found in the center, i.e., in the midline of the oropharyngeal region, where measurement resolution is calculated at below 1 mm. A computer algorithm calculates the actual location of the receiver coil as it moves in xy space over time.

Figure 15 The 3-D Carstens EMA system. The head mount contains the transmitter coils; receiver coils are placed on the structures to be measured. (Reproduced with permission from Brigitta Carstens.)

One disadvantage of this system is that only points are measured, and so the behavior of the entire articulator is largely inferred. This is most problematic for the soft tissue structures like the lips, tongue, and velum, whose movements are more fluid than rigid. A second disadvantage is that the data can only be collected at midline and are subject to some error as the articulators rotate left to right. The biggest advantages are the rapid tracking rate and the abililty to track multiple articulators simultaneously. In addition, actual tissue points are measured; tissue motion or compression can be directly measured. Because of these two features, it is possible to measure interaction among the articulators and ask questions about interarticulator timing and programming.

The 3-D Articulograph, AG500 (EMA) (Carstens, Inc.) The 3-D EMA system uses six transmitter coils placed in a spherical configuration on a cube-shaped structure that surrounds the subject's head (see Figure 15). The transmitter coils produce

alternating magnetic fields of different frequencies, which allow their distances from the receiver coils to be tracked in xyz space, including translation and two rotation angles. The receivers can be placed anywhere within the region of interest. The spatial resolution is better than 1 mm and rotation is detected at about 1 degree of accuracy. This system, in the final stages of development, will include 3-D directionality of the tracked motion trajectories, compensation for head movements, and conversion of data into a head-based coordinate space.

The biological hazards of EMA are small. The articulometer uses fairly short exposure times and low field strengths. However, its use is not recommended with pregnant women, and the machine contains a warning: 'Strong magnetic fields may pose a risk to the health of a subject. To avoid such risks, the eld strengths produced by any EMA system should be measured and compared to published permissible exposure standards.'

X-ray Microbeam

The X-ray Microbeam facility is located at the University of Wisconsin, Madison, WI. The X-ray Microbeam uses an extremely thin X-ray beam to track the motion of small gold pellets that are affixed to one or more articulators using dental adhesive. The beam is 0.4 mm thick, and the pellets are 2–3 mm in diameter. Gold pellets are used because gold is an inert metal and because, as the X-ray dosage is very small, only a very dense metal can be detected. The system was designed to reduce radiation dosage to well below that of a dental X-ray in order to both avoid radiosensitive areas such as the eyes and reduce secondary photon scatter. The X-ray beam focuses primarily on the pellets so that the surrounding tissue receives only minimal radiation.

The 2-D position of the beam is computer controlled. As with traditional X-rays, the X-ray Microbeam originates on one side of the subject, passes through the subject's head, and is detected by a scintillation counter on the far side. Up to 1000 pellet positions are sampled per second. Thus, if 10 pellets are used, they can each be sampled 100 times per second. Differential sampling rates are also possible. The pellets are sampled initially in rest position to determine baseline xy displacement. A computer algorithm causes the beam to scan the area in which the pellet is predicted to move. The prediction is based on the pellet's previous displacement, velocity, and acceleration. Each pellet is scanned in turn. Positioning accuracy of the beam is 62 microns.

There are several advantages to the X-ray Microbeam. The rapid rate and accuracy of tracking make this an excellent system for examining timing-related coarticulatory effects, kinematic parameters such as velocity and acceleration, and the intercoordination of the articulators. In addition, the technique is unobtrusive, and the low radiation dosage allows for reasonably large datasets to be collected on each subject.

The X-ray Microbeam requires a large support staff and exists in a single location: Madison WI. Therefore, use of this system requires considerable travel for most investigators and their subjects. The machine provides point-tracking information, which is very similar in nature to the EMA data. However, it does expose the subject to radiation, albeit a small amount. Given the limited access to the X-ray Microbeam, this machine may be underutilized in the future. The facility has created a database from its collection, however, which is publicly available from the X-ray Microbeam, University of Wisconsin, Madison, WI, USA. This database is very convenient for those who would like to use point-tracking data and do not have access to an EMA system or the Microbeam itself.

Optotrak

A third point-tracking system, designed to measure surface features, is Optotrak (Northern Digital, Inc, Waterloo, Canada). This device tracks the movement of points in three-dimensional (xyz) space. Thus, Optotrak can measure side-to-side movement as well as anterior-to-posterior and superior-to-inferior movement. The system consists of markers placed on surface structures, sensors that track their positions, and a system unit that controls the timing of the marker emissions and the sensor processing. The markers are lightweight, flat, circular disks that come in two diameters, 7 mm and 11 mm. Embedded in the center of each marker is a small semiconductor chip that emits an infrared signal. Up to 256 markers can be used at one time. A strip of three sensors acts as a camera and tracks the movement of the markers. This is not a video system in which marker positions are filmed. Rather, each sensor contains a lens and signal-processing circuitry that records the infrared emissions of the marker. The sensors are prealigned so that they measure the position of each marker in three-dimensional space.

The instrument is particularly well suited to tracking lip and jaw motions in three-dimensions and examining relationships between them and head position. Its advantage over the other two point-tracking systems is that it provides three-dimensional motion data. The third dimension allows measurement of rotation and is needed for complete understanding of speech kinematics and motor control.

The system's disadvantage is that it is limited to external use, unlike the X-ray Microbeam and articulometer, because its sensors must maintain 'visual' contact with the LEDs. Therefore, it cannot be used inside the mouth and so does not shed light on the inaccessible structures within the vocal tract. Two more disadvantages are common to all point-tracking systems. First, the markers or their attached wires may interfere, at least minimally, with truly natural speech. Second, only fleshpoints are tracked, not the entire structure. For rigid structures like the jaw, the entire structure can be reconstructed. Although the deformation of soft tissue structures like the tongue, lips, and velum is incompletely measured, an adequate number of markers can provide a fairly accurate representation.

Inductance/Impedance Measures

Inductance is the momentum of a current through a wire. The flow of current through a wire creates a magnetic field that surrounds the wire. The magnetic field's strength is proportional to the current. Therefore, changes in the current cause changes in the magnetic field. Conversely, a magnetic field will produce a current in a wire placed within the field. These two effects occur simultaneously, so that a wire that is conducting a current (a conductor) produces a magnetic field, which then induces a new current in the original conductor. The induced current will be in the opposite direction from the original current and 90 degrees out of phase. This effect, called 'reactance,' slows down and speeds up the flow of the original current. An inductive transducer takes advantage of this effect. An increase in current enlarges the magnetic field and slows down the rate of flow. The slower flow then reduces the magnetic field, which increases the flow. The effect only works with alternating current, because a constant magnetic field would slow the current to a constant degree. Only with alternating current does the current flow change in systematic ways. (Baken, 1987). The inductance properties of a coil of wire, i.e., the specific changes in the current, depend on the diameter-to-length ratio of the wire. Thus, stretching or compressing a wire will alter its inductance properties. An application of this phenomenon, discussed later in this article, is the inductance plethysmograph, which is used to measure respiration.

Impedance transduction measures the degree to which an electric current is impeded, or disrupted, by a physiological event. Impedance is a combination of resistance and reactance. Thus, it is closely related to inductance. In this case, an electric current is passed through part of the body. Changes in the conduction of the current reflect changes in body activity rather than changes in the diameter-to-length ratio of the wire. An alternating current source is placed at one electrode, and an impedance detector is placed at another electrode. The physiological event is placed between the two electrodes so that the event will alter the flow of current, causing a change in impedance. Examples of this technique discussed later in this article are the electroglottograph, which measures vocal fold vibration, and the electropalatograph, which measures tongue–palate contact.

Electric current can be passed through the body without sensation or harm if the current is of a sufficiently high frequency and low amplitude. Frequencies that are too low, below the kilohertz range, will cause stimulation of sensory receptors. Amplitudes that are too high will cause heating of the tissue.

Electroglottography (EGG)

The EGG measures the impedance (or rather its inverse, conductance) of the vocal folds as they vibrate during phonation. From that, the device estimates changes in the vocal fold contact area. As the vocal fold contact area increases and decreases during phonation, so does the conductance. Thus, the EGG indirectly measures the vibratory pattern of the vocal folds during speech. When the vocal folds are completely closed, the conductance is high and the vocal fold vibratory pattern is visible. When they are open, conductance is zero and no vibration occurs.

EGG is an analog system, and thus has an infinite sampling rate. The resultant high temporal resolution is a major advantage of the system. EGG provides key information on vibratory patterns such as open quotient, speed quotient, duty cycle, aperiodicity, irregularities, and so forth. Other advantages are that the instrument is comfortable, and no sensation results from the current passing through the tissue. Furthermore, the vocal folds are very inaccessible to measurement. The EGG overcomes that inaccessibility. The electric current used in the EGG is of low amplitude and several MHz in frequency. This ensures that the current will neither produce heat nor be felt. A disadvantage is that the EGG is sensitive to extraneous movement, which requires that the subject does not move.

Plethysmograph

The inductance plethysmograph, currently marketed as Respitrace, measures changing lung volume during respiration and the relative contribution of the rib cage and abdomen. A wire band is fitted around the chest and/or abdomen. As the body expands and contracts during respiration, the wire stretches and compresses. A change in inductance is caused by the

change in body diameter, that is, the length ratio of the wire varies with the crosssectional area of the body part it surrounds. In the plethysmograph, the contributions to breathing of the rib cage and the abdomen are assessed independently and can be combined to calculate lung volume.

The disadvantages of both systems are that the events, lung volume and vocal fold vibration, are derived from other measures, which reduces resolution. In addition, extraneous movements cause variation in inductance and produce unwanted signals. Therefore, the subject must not move. These are not insurmountable problems, however, and impedance transduction has much potential for measuring biological events.

The advantages of these measures are several. They are practical and simple to use. The electrodes are simple to apply, do not penetrate the skin, and are comfortable for the subject. Finally, the electrodes are affected very little by temperature and barometric pressure.

Electropalatography (EPG)

Electropalatography (EPG) is a computer-assisted system that uses impedance transduction to sense and display tongue–palate contact in real time during oral motor activities such as speech and swallowing. The system consists of an external input/output (I/O) module, a PC-based printed circuit card, connecting cables, and software. A custom-fitted 0.5-mm-thick acrylic pseudo-palate is worn by the subject and connected to a computer that samples the electrode activity at 100 Hz or more. Embedded into the pseudo-palate are 62–96 contact electrodes, each about 1 mm in diameter (see Figure 16).

Figure 16 Custom made pseudopalate with 96 electrodes used to record tongue–palate contact.

The grounded pseudo-palate introduces a high-frequency, low-amplitude, harmless current. With the Palatometer activated, a nondetectible DC current is sent through the fine wires to the electrodes that will register tongue–palate contact at a sweep rate of 100 samples per second. The contact information is relayed to the computer and displayed on the monitor in a pattern closely resembling the actual electrode layout on the pseudo-palate. The uncontacted, individual electrodes appear on the screen in a different color from the contacted electrodes. The electrodes sense on-off contact, and the contact information is stored on a dedicated PC as a movie or series of frames using the Palatometer software.

The strength of EPG is that it provides detailed information on tongue–palate contact. The weakness of EPG is that it provides data only during tongue–hard palate contact. Information on the actual movement of the tongue is missing. This system is suitable for and has been used to study tongue movement during applications in linguistics, speech pathology, and swallowing. Linguistics research has studied phoneme-specific contact characteristics and lingual-coarticulatory effects in different languages (Hardcastle *et al.*, 1989). In speech pathology, EPG has been used as a biofeedback tool in articulatory remediation (Fletcher *et al.*, 1991). In swallowing, timing and patterning of tongue–palate contact for different swallowing tasks has been studied (Chi-Fishman *et al.*, 1996).

Imaging Brain Lateralization

B Stemmer, University of Montreal, Montreal, Canada

© 2006 Elsevier Ltd. All rights reserved.

Although there are still debates on the specific networks in the left hemisphere that contribute to language processing, most researchers adhere to the view that 'low-level' processing, including phonological, morphological, syntactic, and semantic processing, predominantly engages the left hemisphere. (*see* **Imaging Brain Lateralization: Words, Sentences, and Influencing Factors in Healthy, Pathological, and Special Populations**.) Right hemisphere involvement or dominance is usually attributed to 'high-level' processing, involving, for example, the comprehension or production of discourse and pragmatic (including social) aspects of language.

Integrating Semantics

Meaning developing from incoming words through spoken or written sentences is integrated rapidly with global discourse-level semantic information, usually within less than 600 milliseconds (for a summary see van Berkum *et al.*, 2003). For example, when hearing a sentence such as *Dutch trains are red*, the semantic content of the sentence (i.e., that Dutch trains are of red color) is rapidly understood. However, at the same time, every person familiar with Dutch trains will also know that this is not true because Dutch trains are, in fact, yellow. In this example, semantic information does not coincide with pragmatic world knowledge. The question, thus, is whether there is a distinction between the integration of linguistic meaning (semantic information) and world knowledge (pragmatic information). Some researchers don't think so. Using functional magnetic resonance imaging (fMRI) scanning and recording of event-related potentials (ERPs), Hagoort *et al.* (2004) compared semantic and world knowledge violations and their correct counterparts using sentences such as *The Dutch trains are yellow/white/sour and very crowded*. Applying fMRI and ERPs to the same stimuli provided the researchers with information on the time course of the ongoing processes as well as on the spatial distribution of the underlying neural substrates. They observed an ERP component (the N400) that is very sensitive to semantic integration processes occurring in a time window between 250 to 550 milliseconds after the critical stimulus for both world knowledge violation and semantic violation. This indicated that lexical-semantic knowledge and general world knowledge were both integrated in the same time frame during sentence interpretation.

Although there are still debates on the specific networks in the left hemisphere that contribute to language processing, most researchers adhere to the view that 'low-level' processing, including phonological, morphological, syntactic, and semantic processing, predominantly engages the left hemisphere. (*see* **Imaging Brain Lateralization: Words, Sentences, and Influencing Factors in Healthy, Pathological, and Special Populations**.) Right hemisphere involvement or dominance is usually attributed to 'high-level' processing, involving, for example, the comprehension or production of discourse and pragmatic (including social) aspects of language.

Integrating Semantics

Meaning developing from incoming words through spoken or written sentences is integrated rapidly with global discourse-level semantic information, usually within less than 600 milliseconds (for a summary see van Berkum *et al.*, 2003). For example, when hearing a sentence such as *Dutch trains are red*, the semantic content of the sentence (i.e., that Dutch trains are of red color) is rapidly understood. However, at the same time, every person familiar with Dutch trains will also know that this is not true because Dutch trains are, in fact, yellow. In this example, semantic information does not coincide with pragmatic world knowledge. The question, thus, is whether there is a distinction between the integration of linguistic meaning (semantic information) and world knowledge (pragmatic information). Some researchers don't think so. Using functional magnetic resonance imaging (fMRI) scanning and recording of event-related potentials (ERPs), Hagoort *et al.* (2004) compared semantic and world knowledge violations and their correct counterparts using sentences such as *The Dutch trains are yellow/white/sour and very crowded*. Applying fMRI and ERPs to the same stimuli provided the researchers with information on the time course of the ongoing processes as well as on the spatial distribution of the underlying neural substrates. They observed an ERP component (the N400) that is very sensitive to semantic integration processes occurring in a time window between 250 to 550 milliseconds after the critical stimulus for both world knowledge violation and semantic violation. This indicated that lexical-semantic knowledge and general world knowledge were both integrated in the same time frame during sentence interpretation.

The neural substrates that were activated when the critical words occurred were identified with fMRI and were all shown to be in the left hemisphere (left inferior prefrontal cortex, BA45 and 47) for both the semantic and the world knowledge violation condition. These findings were viewed as evidence that the left hemisphere, and specifically the left inferior prefrontal cortex, plays a role in the integration of both world knowledge and lexical semantic knowledge.

It seems, though, that at least for the integration of lexical semantic knowledge (pragmatic knowledge has not been investigated), other brain areas – such as the left posterior fusiform gyrus and the anterior temporal lobe bilaterally (Kiehl *et al.*, 2002) – are also implicated. A specific involvement of the right hemisphere in lexical semantic meaning integration has been suggested by Federmeier and Kutas (1999). They used the ERP technique while presenting the critical stimuli to single hemispheres. Participants had to read pairs of sentences with different endings, such as: '*Checkmate,' Rosaline announced with glee. She was getting to be really good at chess/ monopoly/ football*. The target word at the end of the sentence was either an expected word (*chess*) or an unexpected word, thus creating contextual violation. The unexpected word could be from an expected category (*monopoly*) or an unexpected category (*football*). The target words were presented to either the left or the right hemisphere. The authors found a negativity (the N400) for contextual violations. However, this component differed according to the side of presentation. With presentations to the left hemisphere, the negativity was reduced when violations occurred within a category (*monopoly*). With presentation to the right hemisphere, the negativity was of similar amplitude for both within-category and between-category violations. The authors concluded that both hemispheres process message-level meaning but that they use qualitatively different processing strategies in the way new information is integrated into the sentence context. The right hemisphere compares new information directly with the context information and follows an 'integrative' strategy whereas the left hemisphere compares whether the new information matches the expectation that has been built-up and is thus more 'predictive.'

Hemispheric sentence contribution during sentence comprehension is also influenced by the information that the sentence conveys, such as abstract information or information that can be visualized. For example, when reading or listening to high- or low-imagery sentences and making true/false judgments, both hemispheres are implicated, but it seems to be the left hemisphere (intraparietal sulcus, frontal operculum, temporal area) that generates the internal representations that are used in maintaining and communicating the sentence information – possibly reflecting working memory functions (Just *et al.*, 2004).

In summary, lexical semantic and pragmatic information seems to be integrated very quickly and simultaneously during sentence processing. Specific neural substrates in the left hemisphere have been implicated in the integration of both types of information. For lexical semantic integration, involvement of the right hemisphere has also been shown. Little is known, however, about the neural substrates involved in the integration of pragmatic information. It seems that both hemispheres contribute to lexical semantic integration, with each hemisphere possibly using qualitatively different processing strategies to integrate new information into the sentence context.

Discourse-Related Studies

The idea that the right hemisphere is dominant for discourse and pragmatic processing is based on observations with patients who have suffered damage to the right hemisphere. Such patient studies, however, have not provided conclusive evidence for this idea inasmuch as discourse and pragmatic problems have also been observed in patients with bilateral frontal, left frontal, or diffuse damage to the brain. Several explanations for the observed impairments have been proposed and include an inability to appropriately draw inferences, to integrate information, or to construct mental models. We will explore whether neuroimaging techniques have clarified the contribution of each hemisphere to discourse and pragmatic processing.

It is obvious that a text is easier to comprehend when the topic under discussion is a familiar one. This is, in part, because information on familiar topics can be integrated and inferences drawn on these more easily. For example, it can be difficult to comprehend a text about how to use a video recorder when the headline is missing, that is, without a clarification of the general context of the following information. Several neuroimaging studies indicate right hemisphere dominance in tasks in which the theme or topic guides comprehension or requires topic maintenance (Caplan and Dapretto, 2001; St. George *et al.*, 1999). The specific neural substrates activated within the right hemisphere show **rough** overlapping in right inferior frontal and temporal regions. Drawing inferences from a discourse to judge the theme or moral of a story is also associated with right hemisphere activation (orbital part of the inferior frontal gyrus,

BA47; anterior portion of the middle temporal gyrus, BA21) (Nichelli *et al*., 1995). Note that besides right hemisphere activation, the left hemisphere language network is usually also activated, indicating the presence of low-level language processing, such as word retrieval and syntactic parsing. Both hemispheres (especially the dorsolateral prefrontal cortex) seem to be involved when the generation of an inference is necessary to maintain coherence in a text. Once an inference is successfully generated, the right hemisphere takes over to integrate the inference into the internal knowledge base of the reader/writer (Mason and Just, 2004). However, not all tasks that involve making inferences activate the right hemisphere. Deductive and syllogistic verbal reasoning tasks and the judgment of local coherence when reading sentences have been shown to activate specific regions in the left hemisphere (left frontal, left temporal, and left cingulate regions for deductive and syllogistic verbal reasoning and left frontomedian wall, posterior cingulate, and precuneal regions for judging coherence; Ferstl and von Cramon, 2001; Goel *et al*., 1998). One explanation of this left hemispheric involvement is that the generation processes involved in these tasks operate on easily available information and are relatively automatic. No high-level integration processes are necessary.

The comprehension of discourse and pragmatic aspects are also influenced by the way stress and intonation are used, and some models have proposed that prosody is lateralized to the right hemisphere, although the evidence is not clear cut (for a review see Baum and Pell, 1999). Right hemisphere activation is reported by one functional imaging study investigating recognition of emotional prosody by applying stress and intonation to words or sentences that conveyed the speaker's emotional state (anger, surprise, sadness, or happiness) (Buchanan *et al*., 2000). Increased activation was reported in the right inferior frontal gyrus and right inferior parietal regions. Considering that the right prefrontal cortex has generally been implicated in the processing of emotions, it remains open whether the observed right hemisphere activation is specific to prosody or to the emotional component involved. In a review of the literature, Baum and Pell (1999) concluded that a clear-cut division that assigns prosody to the right hemisphere is unwarranted.

Investigating the Pragmatics of Communication

When we talk about the pragmatics of communication, we talk about language in use and in context. That not everything that is said is meant in a direct, straightforward way is best exemplified when we use figurative language such as metaphors or irony. To comprehend the information the other person wants to convey entails inferring the other person's intention, or attributing mental states.

Attributing Mental States

We constantly draw on our experience and knowledge and on information from the environment to make sense of the world. Taking a different perspective and inferring the mental state of other people (that is, their intentions, knowledge, beliefs, or desires) is fundamental to successful interaction. Several neuroimaging studies have investigated the neural substrates underlying the attribution of mental states (such as discussed in the theory of mind; for a summary see Abu-Akel, 2003; Gallagher and Frith, 2003). Although neuroimaging studies do not always report corresponding regions of activation, there are three areas that have been reported to be consistently active in theory-of-mind tasks (for a summary see Gallagher and Frith, 2003, and Figure 1): the medial prefrontal cortex (in some studies slightly left lateralized), the right or bilateral superior temporal sulci, and the temporal poles bilaterally. The medial prefrontal cortex is associated with the ability to represent mental states that are 'decoupled' from reality. The superior temporal sulcus seems involved in processing explicit behavioral information such as the perception of intentional behavior, and the temporal poles have been implicated in the retrieval from memory of personal experiences.

Another interesting observation is that the brain reacts in characteristic manners when we predict other people's actions as opposed to when we predict our own. Predicting one's own actions preferentially activates the left dorsal premotor area, whereas predicting other people's actions activates the left paracingulate cortex, right superior temporal sulcus, and cerebellar vermis (Ramnani and Miall, 2004). Interestingly, when observing one's own action brain activation (left parietal, left operculum, and bilateral premotor cortex) starts earlier compared with watching other people's actions (Grèzes *et al*., 2004). The reason could be that when one observes one's own action, there is a closer match between simulated and perceived action than there is when one observes the actions of others.

It is important to realize that different types of theory-of-mind tasks may activate different neural substrates and that activation can occur at different points in time. Investigations using the EEG/ERP technique have identified two negative ERP components:

Figure 1 A summary and display of areas of activation found in the medial prefrontal cortex (anterior paracingulate) during theory-of-mind tasks. Also displayed are areas of activation in other areas of the medial prefrontal cortex (the anterior cingulate cortex) found to be associated with autonomic arousal, cognitive demand, and response conflict. [29] Critchley H D *et al.* (2000). 'Cerebral correlates of autonomic cardiovascular arousal: a functional neuroimaging investigation in humans.' *Journal of Physiology London 523*, 259–270. [30] Critchley H D *et al.* (2001). 'Neural activity in the human brain relating to uncertainty and arousal during anticipation.' *Neuron 29*, 537–545. [31] Duncan J and Owen A M (2000). 'Common regions of the human frontal lobe recruited by diverse cognitive demands.' *Trends in Neuroscience 23*, 475–483. [32] Barch D M *et al.* (2001). 'Anterior cingulate cortex and response conflict: effects of response modality and processing domain.' *Cerebellum Cortex 11*, 837–848. Taken from Gallagher HL & Frith C D (2003). 'Functional imaging of 'theory of mind'.' *Trends in Cognitive Science 7(2),* 77–83. © Elsevier, with permission.

one between 270 and 400 milliseconds when decoding others' emotional mental states and another around 800 milliseconds when making belief judgments (Liu *et al.*, 2004; Sabbagh *et al.*, 2004). Whereas the generator for the early negativity was identified in the right hemisphere (right orbitofrontal cortex and right anterior medial temporal cortex), the late negativity was generated in the left hemisphere (left orbitofrontal cortex). Orbitofrontal activation has been associated with emotional processing (Damasio *et al.*, 2000) whereas the right medial temporal activation would fit with other studies that implicate this region in theory-of-mind tasks.

Finally, the ability to infer other people's mental states has also been investigated in schizophrenic and autistic patients during imaging. Based on a nonverbal comic strip depicting a simple story, schizophrenic patients had to attribute intentions to others (Brunet *et al.*, 2003). Compared with healthy participants, schizophrenic patients did not activate the right prefrontal cortex, a region that has been shown in several studies to be implicated in theory-of-mind tasks. Autistic patients, on the other hand, demonstrated activation patterns similar to those of healthy people in right hemispheric and bilateral regions, except that there was generally less activation (Castelli *et al.*, 2002).

Investigating Figurative Language

Right hemisphere involvement in figurative language (such as in the comprehension or production of metaphors, humor, and idioms, or the making of requests) has been claimed ever since it was observed that some people with damage to the right hemisphere show problems interpreting figurative language appropriately. The idea of right hemisphere involvement in the comprehension of figurative language also has its roots in psycholinguistic models of figurative language comprehension.

A lively debate in psycho- and neurolinguistics has surrounded questions such as whether metaphors can be understood as quickly and automatically as regular sentences, whether specific processing stages are necessary for their comprehension, whether the same processes underlie the comprehension of different types of metaphors, and whether such differences are represented in different parts and sides of the brain (for a summary see Glucksberg, 2003). Despite the numerous psycho- and neurolinguistic studies, only a few neuroimaging studies have directly investigated this question. In a positron emission tomography (PET) study, participants had to make plausibility judgments while listening to sentences (plausible metaphors, implausible metaphors) and to

Figure 2 Displayed are averaged activation maps based on subjects viewing *Seinfeld* (upper panel) and *The Simpsons* (lower panel) sitcoms. A functional dissociation between humor detection and humor appreciation was described. In the coronal brain images, the left side of the image corresponds to the left hemisphere. In both studies, humor detection led to greater activation in the left posterior middle temporal gyrus and the left inferior frontal gyrus. By contrast, humor appreciation yielded greater activation bilaterally in the insular cortex and the amygdala. Taken from Moran *et al.* (2004). 'Neural correlates of human detection and appreciation.' *Neuroimage 21*, 1055–1060. © Elsevier, with permission.

random word strings. Greater activation in the right hemisphere (right inferior frontal gyrus, the right premotor cortex, and the right posterior temporal cortex) was found when comparing plausibility judgments of metaphoric sentences with those of literal sentences (Bottini *et al.*, 1994).

Understanding jokes is, in a way, similar to metaphoric or other figurative language in that what is meant is not said. Comprehending jokes, however, involves more than just understanding what is meant. Neuroimaging studies using fMRI have identified dissociated neural substrates for a cognitive and an affective element of humor (Goel and Dolan, 2001; Moran *et al.*, 2004; see Figure 2). Unfortunately, the neural substrates identified by the two groups do not correspond. For the affective component, one study described the medial ventral prefrontal cortex and bilateral cerebellum (Goel and Dolan, 2001) whereas the other study found the bilateral amygdala and bilateral insula to be activated (Moran *et al.*, 2004). The left insular region (BA44/4) was also activated in the Goel and Dolan study (2001), but it was related to phonological, not affective, joke processing. For the cognitive component, both studies identified the posterior middle temporal gyrus to be implicated, but in the right hemisphere in one study (Moran *et al.*, 2004) and in the left hemisphere in the other (Goel and Dolan, 2001). The left posterior inferior temporal gyrus (Goel and Dolan, 2001) and the left inferior frontal gryus (Moran *et al.*, 2004) were also involved.

Taken together, the right hemisphere contributes to keeping track of the topic or theme of a discourse and to drawing high-level inferences, including attributing mental states to others and interpreting figurative language, and to integrating meaning into a larger discourse or social context. The right hemisphere thus seems to be indispensable for successful pragmatic and social communication. Inconsistencies remain, however, concerning the specific neural substrates or networks involved. It is also possible that not all neural substrates and networks involved have yet been identified.

In addition to its role in low-level language processing, the left hemisphere is also involved in deductive and syllogistic reasoning processes and in establishing local coherence, that is, in low-level inferencing processes (for a summary see Bookheimer, 2002).

Imaging Brain Lateralization: Words, Sentences, and Influencing Factors in Healthy, Pathological, and Special Populations

Classically, the brain has been divided into two sides – the right and the left. To the inexperienced eye, both sides look the same, although a closer look reveals subtle anatomical differences. For example, an anatomical area situated at the end of the superior temporal gyrus, the planum temporale, is much larger on the left than its right-sided homologue. In addition, Broca's speech area and the primary auditory cortex (Heschl's gyrus) are larger in the left hemisphere than in the right (for a summary, see Toga and Thompson, 2003). These anatomical structures surround or overlap brain regions important for language. It seems natural to ask whether these anatomical or structural differences are in any way reflected at a behavioral, functional, or even biochemical level (for a detailed discussion, see Hugdahl, 2000). Early models of brain asymmetry tried to establish such relationships primarily by observing the language performance of patients with damage to specific regions of the brain or behavioral tasks performed with healthy individuals. Based on such data, language production and some aspects of syntactic processing were suggested to be localized in the left side of the brain, and indeed, in particular, to areas of the inferior frontal gyrus (Broca's area). Language comprehension was localized in the posterior temporal–parietal region (Wernicke's area) (Figure 1).

Since the advent of neuroimaging techniques, new possibilities have opened up to investigate anatomical/structural and functional/behavioral relationships. Although these techniques allow, to some degree, to watch 'the brain in action,' each has its own strengths and weaknesses. As is the case with all complex techniques, data from each of these imaging methods need to be interpreted with those particular strengths and weaknesses in mind. The most common of these neuroimaging techniques are positron emission tomography (PET) and functional magnetic resonance imaging (fMRI); these are both particularly appropriate for discovering *where* in the brain specific events happen. Techniques based on electrical or magnetic signals (electroencephalogram (EEG) or magnetoencephalogram (MEG)), on the other hand, are more suitable in determining *when* they happen.

Research on the mind/brain–language relationship has not only produced a wealth of insights but also raised new questions or rephrased old ones. This article focuses on research that has used neuroimaging techniques (PET, fMRI, and EEG) to investigate language and, more specifically, explores what neuroimaging research has contributed to our understanding of what happens in the 'left' and 'right' side of the brain at the word and sentence level.

Imaging Single Word Lateralization

Imagine that you see a string of symbols such as *oppmtrgt* or *flower*. Approximately 200–250 ms after seeing these symbols or hearing the corresponding sounds, your brain has determined that one is a word and the other is a nonword; slightly more time is needed if the word is less frequently used (such as flower vs. tungsten). Approximately 400 ms after seeing or hearing a word, the brain has assigned some meaning to it. Where in the brain do these fast processes take place? Is one hemisphere more implicated than the other in these abilities? Generally, when people listen to speech stimuli, such as syllables, single words, pseudowords, foreign words, or sentences, most studies report involvement of both hemispheres; only a few report slightly more activity in the left hemisphere (Binder and Price, 2001) (Figure 2). During these listening tasks, the brain regions consistently activated according to fMRI or PET studies

Figure 1 Anatomical sites of the classical language areas identified in a transparent surface model of the human cerebral cortex. Broca's speech area (green) and Wernicke's language-comprehension area (blue) are identified on a transparent surface model of the human cerebral cortex. All cortical regions are interconnected through the corpus callosum (yellow) with corresponding systems in the opposite brain hemisphere. From Toga A W and Thompson P M (2003). Figure 2 Summary of the results of functional imaging studies on word repetition, word retrieval, and word reading. The top row shows brain areas activated during the acoustic processing of heard words and visual processing of written words. Activation is predominantly bilateral. The second row, left side, shows brain activation related to the phonological processing of speech sounds relative to environmental sounds. In the center, semantic decisions relative to phonological decisions on the same words are shown, and the right side shows activation associated with retrieving the name (via lexical semantics) relative to seeing visual controls and saying 'Okay' or 'Yes.' Note that the activation is predominantly left lateralized. The third row presents transverse slices and shows activation in the left anterior insula and left frontal operculum during phonological output. Bilateral activation is shown in the fourth row and exhibits motor areas for articulation and auditory processing of spoken response for reading aloud relative to reading silently. The red arrows connect these areas to indicate the proposed model of auditory and visual word processing. From Price C J (2000). 'The anatomy of language: contributions from functional neuroimaging.' *Journal of Anatomy 197(5)*, 335–359. Reproduced with permission from Blackwell Publishing.

are in the superior temporal gyrus (including the planum temporale) of both hemispheres. Based on these observations, it has been suggested that the superior temporal region in both hemispheres plays a critical role in auditory perception but is less implicated in processing lexical–semantic or syntactic information. Lateralization to the left is associated with other aspects of auditory processing. For example, when healthy volunteers listen to tones, sounds of animals, instruments, and words, the highest activation for the

perception of words is exhibited within the left superior temporal sulcus and in the left inferior frontal gyrus.

Phoneme processing is also lateralized to the left side of the brain. Areas of brain activation during phoneme processing involve the left frontal operculum (around the anterior insula and BA45) and a more posterior dorsal region near the inferior frontal gyrus/premotor boundary (BA44/6). Although the left supramarginal gyrus also seems to contribute to phoneme processing, this region is also activated in a variety of other tasks, such as pitch discrimination of auditory tones, reading visually presented words relative to picture naming, and reading pseudowords relative to words (for a summary, see Binder and Price, 2001).

Word generation (exemplified by tasks such as 'Name all words that start with F' or 'Name all animals you can think of') is a frequently used paradigm in functional imaging studies. This task involves phonological but also word retrieval processes and consistently produces activation in the left hemisphere (the frontal operculum and inferior frontal gyrus (BA44–47)). These areas overlap with regions that are also activated in phoneme processing. Additional areas of activation have been described in the posterior part of the middle frontal gyrus and inferior frontal sulcus, the mid-dorsal part of the precentral sulcus (BA6, 8, and 44) and the left posterior temporal lobe (BA37). Some of these specific regions in the left hemisphere (left frontal operculum and the left posterior ventral temporal area) are activated independently of the type of stimulus cue or the modality in which the stimulus is presented. Evidence for this comes from studies on blind subjects when reading Braille (Büchel *et al.*, 1998) or when comparing active generation of words with listening to words or semantic judgments on heard words (Warburton *et al.*, 1996).

Tasks involving word meaning also invoke activation that is strongly lateralized to the left hemisphere. The single most consistently activated area within the left hemisphere is the angular gyrus (BA39). This region has been interpreted as a multimodal 'convergence' zone involved in storing or processing very abstract representations of sensory experience and word meaning. Other regions that are frequently activated with the meaning of words are those associated with memory functions, such as the dorsal prefrontal cortex (including medial aspects of BA8 and 9) (for a summary, Binder and Price, 2001).

It was previously mentioned that the extraction of word meaning is preferentially processed in the left hemisphere. The question arises, however, whether or not this is true for the whole spectrum of words ranging from abstract words (such as 'creativity') to concrete words (such as 'television'). Several nonimaging studies – often within the context of specific theories of word processing such as the dual coding model – have investigated the neural bases of abstract and concrete word processing. The dual coding model assumes that abstract words are represented only in verbal symbolic codes, whereas concrete words additionally activate nonverbal, imagery-based representations (Paivio, 1991). Within this framework, it has often been assumed that abstract words are represented in the left and concrete words in the right hemisphere. Neuroimaging studies investigating concrete and abstract nouns, however, have not shown such a clear-cut division. Most studies comparing concrete versus abstract nouns report increased activation for concrete nouns predominantly in the left hemisphere, and several studies have found greater activity for abstract than concrete words in the right hemisphere (for a summary, see Fiebach and Friederici, 2003) (**Figure 3**). Other researchers report no difference in activation between abstract and concrete nouns in the two hemispheres but differences within the left hemisphere. For example, a fMRI study using a lexical decision task (Fiebach and Friederici, 2003) reported a double dissociation within the left hemisphere: abstract words elicited increased activation in the pars triangularis (BA45) of the left inferior frontal gyrus and concrete words led to an activation increase in basal regions of the left temporal lobe.

Taken together, neuroimaging studies have shown that auditory perception involves both hemispheres, whereas phoneme processing and word processing engage predominantly the left hemisphere, regardless of the modality in which the stimulus is presented. The findings are inconsistent with regard to the processing of words with specific characteristics, such as concrete versus abstract words.

Imaging Sentence Lateralization

When listening to or reading sentences, we constantly determine 'Who did what to whom?' That is, we establish the meaning of the sentence. Is there a hemisphere that is dominant for these processes, and are there areas in the brain that are specialized for syntax alone? Traditionally, damage to the anterior regions of the left hemisphere has been associated with language problems as observed in patients with Broca's aphasia. Broca's aphasia was typically linked with damage involving the left inferior frontal cortex (BA44/45), leading to the idea that this was an area specialized for syntactic processing. Do imaging data support this idea? To test this idea with

Figure 3 Fiebach and Friederici (2003) visualized brain areas exhibiting greater activity for concrete words than for abstract words (A) or greater activity for abstract than for concrete words (B). Each colored dot represents the results of a particular study reviewed by Fiebach and Friederici. Note that medial and subcortical activations are not displayed. Reproduced with permission from Fiebach C J and Friederici A D (2003). 'Processing concrete works: fMRI evidence against a specific right-hemisphere involvement.' *Neuropsychologia 42*, 62–70. © Elsevier.

neuroimaging, one would need to design tasks that tease out syntactic processing alone. This, however, would be very difficult to accomplish, and it is thus not surprising that the different approaches and stimuli that have been used have not produced consistent activation patterns.

Some researchers compared simple versus complex sentences and reported activations predominantly in the left hemisphere (Broca's area (BA44/45), occasionally extending to BA47, 6, 9; left angular/supramarginal gyri (BA39, 40); and cingulate gyrus (BA23, 24, 31, 32)) (for a summary, see Kaan and Swaab, 2002). However, not all such studies have reported significant activation in Broca's area – an inconsistency that suggests that this region is not necessarily implicated in all aspects of syntactic processing. For example, Friederici *et al*. (2003), using fMRI, compared correct sentences to sentences with syntactic or semantic violations. Bilateral activation (midportion of superior temporal gyrus, insular cortices, and posterior superior temporal gyrus) was observed in sentences containing semantic violations, whereas sentences with syntactic violations activated only the left hemisphere (anterior and posterior portion of the superior temporal gyrus, left posterior frontal operculum adjacent to BA44, and basal ganglia). Activation in classical Broca's area was not observed.

Another question frequently asked concerns the relationship between syntax and semantics. Do they activate common or separate brain areas? Alas, neuroimaging research has produced mixed and partially inconsistent results. An interaction between syntax and semantics was reported in several regions of the left hemisphere, including Broca's region, the left cingulate, left posterior middle frontal gyrus, and left inferior parietal cortex (for a summary, see Ben-Shachar *et al*., 2004). It remains unclear, however, whether Broca's and Wernicke's areas are activated conjointly or whether each region is activated individually, and how specific this is for either syntax or semantics. Another series of studies also reported activation in the right hemisphere and indeed in the right homologue of Broca's and Wernicke's regions. A consistent set of brain regions was activated when comparing 'movement' sentences ('John gave the red book to the professor from Oxford'/ 'John gave to the professor from Oxford the red book') to 'non-movement' sentences while manipulating topicalization and wh-questions (Ben-Shachar *et al*., 2004). In both conditions, activations included regions only in the left hemisphere (inferior fontal gyrus and ventral precentral sulcus) and bilaterally (posterior superior temporal sulcus). It was hypothesize that the bilateral posterior temporal activation was related to maintenance of the 'moving element' in memory.

Various researchers have suggested that the amount of material that is processed (i.e., the 'processing load') needs to be considered. In this context, the question has been raised to what degree Broca's area is involved in memory processes. For example, a sentence such as 'The student who imitated the professor dropped his books' (subject relative clause) seems to require less working memory resources than 'The student who the professor imitated dropped his books' (object relative clause). Several studies report activation in Broca's and Wernicke's areas. Investigating center-embedded subject- and object-relative clauses, McDonald and Christiansen (2002) found increased activation in both Broca's *and* Wernicke's areas for object-relative clauses compared to subject-relative clauses and for subject-relative clauses compared to active conjoined clauses. Similarly, comparing subject-relative clauses in Japanese (a verb-final language) and manipulating center-embedded vs. left-branching structures showed an increase in activation in the left inferior frontal gyrus (BA44 and BA45), the posterior portion of the left superior temporal gyrus (BA22; i.e., Wernicke's area), and the left dorsolateral prefrontal cortex (posterior part of BA9) (Inui *et al*., 1998). In Japanese, center-embedding with canonical word order seems to entail a greater working memory load than fronting an object in

noncanonical word order. However, a series of PET studies comparing center-embedded object relatives ('The juice [that the child spilled] stained the rug') vs. right-branching subject relatives ('The child spilled the juice [that stained the rug]') performed by Caplan and colleagues consistently showed increased activation in Broca's area only, although the exact locus of activation withinBroca's area varied: the pars opercularis (BA44) (Caplan *et al*., 1998; Stromswold *et al*., 1996) and the pars triangularis (BA45) (Caplan *et al*., 1999, 2000).

Taken together, and consistent with some behavioral studies, these neuroimaging studies indicate that Broca's area is not involved in all aspects of syntactic processing. In addition, although functional neuroimaging studies investigating syntactic processing report predominantly left hemisphere activation, bilateral and right hemisphere activation is also reported. The observed activation patterns may indicate that different aspects of syntactic processing activate different parts of a network in both hemispheres (Kaan and Swaab, 2002). For example, incoming words of a sentence activate phonological, syntactic, and semantic information that may be reflected in the activation of the middle and superior temporal lobes in the left hemisphere. Other left hemisphere activation, such as that of the anterior temporal lobe, may reflect accessing stored information or encoding of information for later use. Increased processing load requires storing nonintegrated material in which the inferior frontal gyrus (Broca's area) might be implicated. Bilateral or right hemisphere activation may reflect aspects of prosody, discourse, and pragmatic integration processes but also control and memory processes.

Imaging Hemispheric Lateralization in Patients

Other questions of interest concern whether changes in language lateralization occur after damage to specific brain regions, such as in patients suffering from intractable epilepsy, children with extensive brain damage in early childhood, schizophrenic patients, or patients recovering from a stroke.

Defining Hemispheric Lateralization for Presurgical Patients

The gold standard to determine language lateralization in patients who need to undergo surgical intervention, such as tumor removal or epilepsy surgery, has been the Wada test, a procedure during which one hemisphere is selectively anesthetized. Since fMRI has become more available, the question as to whether noninvasive fMRI provides similar or possibly even better information than the Wada test has been raised. This seems, indeed, to be the case. Studies are consistent in their evaluation that there is good agreement between the Wada and the fMRI procedure (Adcock *et al*., 2003; Bazin *et al*., 2000; Binder *et al*., 1996; Gaillard *et al*., 2002; Sabbah *et al*., 2003; Yetkin *et al*., 1998). Some researchers even reported more sensitivity of the fMRI technique concerning the involvement of the nondominant right hemisphere (Adcock *et al*., 2003). It should also be noted that due to time constraints of the anesthetic agent used in Wada testing, rather simple language tasks had to be used. This limitation does not pertain to fMRI, which allows for more flexibility in language testing. Finally, several neuroimaging studies noted the higher variability of language dominance in epilepsy patients (Adcock *et al*., 2003; Sabbah *et al*., 2003; Springer *et al*., 1999).

Language Lateralization in Other Patients

It has been an accepted common wisdom that children recover faster or better after their brains have been damaged than do adults. For obvious reasons, there are only few neuroimaging studies with young children. One such study monitored the recovery of language abilities in a boy with intractable epilepsy before and after the left hemisphere was removed (Hertz-Pannier *et al*., 2002). After surgery, the boy showed rapid recovery of receptive language functions but slower and incomplete recovery of expressive language and reading as measured by fMRI. A year later, a shift of language-related networks to the right hemisphere (right inferior frontal, temporal, and parietal activation) during expressive and receptive tasks was observed in agreement with the notion of the superior plasticity of the child's brain and the ability of the right hemisphere to take over some expressive language functions. Another study (Holland *et al*., 2001) investigated developmental patterns of brain activation associated with a verb-generation task in 13 healthy children/adolescents aged 7–18 years using fMRI. The regions of activation found were similar to those of adults with predominantly left hemisphere activation (inferior frontal gyrus). Similar results were reported by Balsamo *et al*. (2002). Generally, it appears that the degree of lateralization increased with age and proficiency in language skills, leading to a shift in activation toward greater lateralization in the left hemisphere (Holland *et al*., 2001).

In schizophrenic patients, increased activation in the right hemisphere in response to low-level language tasks has been consistently reported (Artiges *et al*., 2000; Greene *et al*., 2001; Sommer *et al*., 2003). Some researchers have hypothesized that the increased activation reflects a failure to inhibit

Figure 4 Results of a PET study in left hemisphere stroke patients with various aphasic syndromes. The patient group with subcortical and frontal lesions improved substantially and activated the right hemisphere (inferior frontal and right superior temporal gyri) at baseline. Left superior temporal gyrus activation occurred at follow-up. Patients with temporal lesions improved only in word comprehension and activated the left Broca area and supplementary motor areas at baseline. Precentral gyrus bilaterally and right superior temporal gyrus were activated at follow-up but not the left superior temporal gyrus. Reproduced with permission from Heiss *et al.* (2003). 'Disturbance and recovery of language function: correlates in PET activation.' *Neuroimage 20(1)*, 542–549. © Elsevier.

nondominant language areas in patients suffering from schizophrenia (Greene *et al.*, 2001; Sommer *et al.*, 2003).

Clinical recovery from aphasic syndromes can be observed over weeks, months, and even many years after a stroke. Imaging studies have tried to elucidate the neural mechanisms underlying this recovery (for a review of recovery and PET studies, see Heiss *et al.*, 2003) (Figure 4). It has been suggested that recovery in right-handed, left hemisphere language-dominant patients includes undamaged portions of the language network in the left hemisphere and, to a lesser extent, homologous right hemisphere areas (Rosen *et al.*, 2000). Although there might be some contribution by the right hemisphere, it is the reactivation of areas in the left hemisphere that seems essential for recovery of language functions. Predominant activation of structures in the affected hemisphere have been related to good recovery (Heiss *et al.*, 2003).

Interestingly, pharmaceutical intervention in aphasic stroke patients with piracetam (a nootropic agent that has been shown to generally enhance cognitive functions in some patients) has been shown to improve language performance. This, in turn, was reflected in an increase in activation in the left hemisphere (left transverse temporal gyrus, left triangular part of the inferior frontal gyrus, and left posterior temporal gyrus), whereas a trend toward a decrease in activation was observed in the right hemisphere (right inferior frontal gyrus) (Heiss *et al.*, 2003).

Imaging Special Populations

In addition to investigating the contribution of each hemisphere in patient groups, neuroimaging studies have also investigated whether the brain is lateralized differently in people with particular characteristics, such as in people using sign language or people who know more than one language.

Left hemisphere specialization for language has usually been demonstrated with regard to the vocal tract as the primary articulator. However, what if the articulator consists of hands, such as used by deaf users of American Sign Language? Whereas some functional neuroimaging studies have reported largely left-lateralized brain activity for signing, others have shown more right hemisphere involvement than is seen in spoken language (for a summary, see Corina *et al.*, 2003). This discrepancy has been attributed to interpretation problems due to different demands of the motor system involved in signing. Corina *et al.* (2003) performed a PET study using a lexical–semantic word generation task in deaf signers. They observed activation in the left hemisphere (dorsolateral prefrontal cortex (BA46)), dorsal operculum (pars triangularis and opercularis (BA44/45)), and ventral operculum (par orbitalis (BA47)) and concluded that linguistic–semantic processing relies on left hemisphere regions regardless of the modality in which a language is realized.

Numerous neuroimaging studies have investigated brain activation in people who know more than one

language. Inconsistent results are found, however, when comparing these studies. Some researchers report no interhemispheric difference for different languages (Klein *et al*., 1999), whereas others report language-sensitive regions in second languages exclusively in the left hemisphere (Kim *et al., 1997*) or in both hemispheres (Dehaene *et al*., 1997), or report different findings for different participants (Chee *et al*., 2001). Reasons for these inconsistent results are probably due to variables that were not accounted for or are inconsistent in these studies; these include different scanning techniques; different tasks, stimuli, and paradigms used; different languages investigated; differences in proficiency level; differences in the age of acquisition of the nonnative language; differences in length of exposure to the second language; lack of distinction between male and female participants; and differences in methods of analyzing the neuroimaging data (e.g., ROI, individual vs. group data). Considerable variability among subjects in the precise spatial location, spatial extent, and magnitude of these activations has also been reported (for a summary, see Binder and Price, 2001). The importance of distinguishing the level of processing evoked by the task has been noted by Pillai *et al*. (2003). For example, right hemisphere activation occurred only in a phonological (rhyming) task and not in a semantic (verb–noun association) task in the nonnative (but not native) language. Involvement of the right hemisphere appears to be related to the cognitive demands of the tasks and possibly to the level of proficiency (Perani *et al*., 1998). In fact, level of proficiency has been shown to be more important than age of acquisition in eliciting specific patterns of brain activation. Left hemispheric dominance for the native as well as the nonnative language for high-proficiency adults who had acquired their second language late in life has been described by Perani *et al*. (1998). In addition, in these adults, some right hemisphere activation for one but not the other language was seen. These findings contrasted with adults exhibiting low language proficiency who showed different areas of activation for both languages only within the left hemisphere, regardless of age of acquisition of the nonnative language. Another factor that needs to be considered is which languages are compared. For example, in bilinguals, some right hemispheric involvement was found when reading Chinese, whereas reading in English recruited only regions in the left hemisphere (Liu and Perfetti, 2003). Generally, there seems to be little support for the hypothesis that languages learned later in life entail more right hemispheric involvement as both the native and the nonnative language recruit large brain areas in the left hemisphere (Vingerhoets *et al*., 2003).

Taken together, there is no evidence from imaging studies to support a specific role for the right hemisphere in bi- or multilingual people. Note, however, that we cannot draw any conclusions from these studies concerning the involvement of the right hemisphere or the interaction between the two hemispheres during the *process of learning* a foreign language at different stages in life.

Imaging Gender

A long-debated issue concerns an old hypothesis that language functions are more lateralized to the left side of the brain in men and represented more bilaterally in women. It has been shown that the left planum temporale is much larger than its right homologue in males, whereas in females this difference is not significant. This observation seems to provide some anatomical support for reduced asymmetry of lateralization for females for language tasks (Kulynych *et al*., 1994). However, neither nonimaging studies nor imaging studies have yielded consistent results (for a summary, see Binder and Price, 2001; Kansaku and Kitazawa, 2001; Kimura, 2000). Some neuroimaging studies that investigated low-level processing using a verb generation task, word completion task, or semantic word judgment task reported no lateralization differences in men or women (Buckner *et al*., 1995; Jaeger *et al*., 1998). Others, however, using rhyming judgments or passive listening to spoken narratives, found more bilateral activation in women than in men (Kansaku *et al*., 2000; Phillips *et al*., 2000).

Aside from methodological differences, another reason for these discrepant findings could be the different types of stimuli used and different task demands. In addition, many of these neuroimaging studies relied on group data. There is, however, evidence for high individual variation, as shown in a study by Vikingstad *et al*. (2000). Individual data demonstrated that the lateralization index varied continuously from left hemisphere dominant to bilateral representation. In males, language was primarily lateralized in the left hemisphere. In females, approximately half showed left lateralization and the other half bilateral representations. There is thus a possibility that more women than men show bilateral activation in language tasks. Lacking more evidence, however, there is no clear picture about language lateralization in men and women.

Imaging Handedness

There is a widely held belief that language is lateralized in the left side of the brain in right-handed

people and in the right side in left-handers. Research, however, tells a somewhat different story: language is lateralized in the left in the majority of right- and left-handers. Functional imaging studies using low-level language tasks consistently report that in approximately 96% of right-handers, speech and language are lateralized to the left, and in the remaining 3% they are lateralized to the right or bilaterally. In left-handers, 70% show left lateralization and 30% right or bilateral lateralization (Pujol *et al.*, 1999; Szaflarski *et al.*, 2002; Toga and Thompson, 2003). IIn addition, family history of sinistrality strongly influences personal handedness and scores on the language laterality index (Szaflarski *et al.*, 2002). Although these studies argue for a strong relationship between handedness and side of language lateralization, due to a lack of studies it would be premature to conclude that this relationship also holds at higher levels of language processing. Furthermore, brain damage may destabilize this otherwise strong relationship between handedness and language laterality. For example, in right-handed patients with epilepsy, language lateralization proved more variable than in healthy right-handed individuals (Springer *et al.*, 1999). This variability in the epilepsy group was related to weaker right-handedness and also to age of brain injury.

Immigrant Language Education

S Kroon and T Vallen, Tilburg University, Tilburg, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

In a democracy, educational policy objectives and priorities mainly derive from what majority public opinion, as a government's main guide, desires or tolerates (Wright, 1994). This holds also – and in view of the powerless position of minority groups probably even more so – for the objectives of language education policies regarding immigrant minorities. A main characteristic of public opinion is its changeability. Its dynamics are affected and constituted not only by sociocultural, political, and economic circumstances and developments, but also by sporadic incidents, such as 9/11. Moreover, public opinion is substantially influenced by ideas, perceptions, and comments disseminated by mass media, politicians, scholars, and public opinion leaders. Despite their inclination to continuous change, these opinions are nevertheless generally situated within clearly defined domains, containing a limited array of possibilities. With respect to the field of immigrant language education, it can be observed that public, political, and scholarly opinions have been oscillating on a continuum that is marked at the extremes by unconditional assimilation and by unconditional pluralism (Kroon and Vallen, 1997).

Assimilation versus Pluralism

In immigrant language education, the distinction between assimilation and pluralism basically reflects the fundamental dilemma or tension between desirability and feasibility, i.e., the extent to which desirable educational innovations are feasible within a specific societal context, including competing agencies and actors, competing means and goals, competing strategies and procedures, and unending financial and time constraints (Kaplan and Baldauf, 1997).

Assimilation means that immigrant minorities are expected to adapt to mainstream characteristics of the host society and to give up their own identity, language, and culture. In theory, only those immigrants whom one can no longer notice to have once been 'different' from the dominant group are considered to be completely assimilated. Assimilation as a result of an immigrant minority language policy, whether explicitly formulated or functioning implicitly, seems to be an ideal goal for many nation states. As a consequence of recent sociopolitical developments, as well as changing attitudes toward the ongoing processes of immigration, this propensity toward assimilation is gaining more political and practical importance and support. This, of course, has serious consequences for immigrant language education, as will be demonstrated.

Pluralism means that the people in a society function alongside each other without having to give up their ethnic, cultural, and linguistic identity. In an ideal pluralist society, all groups have an inalienable right recognized to retain their culture, language, and traditions, according to their own level of desire. The main reason that no state-sanctioned, completely pluralist society exists is probably that consistently implemented and consequently practiced pluralism – which of course runs the risk of developing into voluntary separatism or involuntary segregation – is unacceptable to the powerful majority. The existence and survival of any society apparently needs a limited degree of social, cultural, and linguistic cohesion and homogeneity, which is in part brought about by a certain level of assimilation or integration of immigrant minority groups (Kroon and Vallen, 1994).

Language as a Right, a Resource, or a Problem

The position taken on the continuum of assimilation and pluralism has important consequences for the perception of immigrant minority languages. Baker (2001) distinguishes three (conscious or subconscious) basic orientations or dispositions regarding multilingualism: language as a problem, language as a right, and language as a resource. In the language as a *problem* orientation, cognitive, personal, social, and political problems can be involved. Multilingualism, i.e., the existence of immigrant minority languages in a given society, is perceived as a handicap that can only be solved by submersion, assimilation, or transition into the majority language. In this view, immigrant minority languages are at both the societal and personal level predominantly connected with problems of poverty, deficits, and underachievement in school, and insufficient social and vocational mobility and integration into the majority culture. The underlying belief is that immigrant minorities could solve most of these problems by learning and speaking the language of the majority. In contrast, the language as a *right* orientation looks upon multilingualism and the individual's right to choose a language as a basic and fundamental human right. This position, realizable at both the individual and group level and at the territorial (both national and international) and domain level, is taken by several writers, such as Skutnabb-Kangas *et al.* (1995) and May (2001); see

Blommaert (2001), however, for a fundamental criticism. Third, in the language as a *resource* orientation, multilingualism is considered a form of capital, both at national and individual levels. This position combines second and foreign language teaching arrangements with immigrant minority language education. Its assumption is that linguistic variation will not lead to separation or disintegration, but that coexistence of national unity and language diversity is possible and desirable.

According to Baker (2001: 375), each of these orientations recognizes

> "that language is not simply a means of communication but is also connected with socialization into the local and wider society, as well as a powerful symbol of heritage and identity. The differences between the three orientations lie in the socialization and identity to be fostered: assimilation or pluralism, integration or separatism, monoculturalism or multiculturalism."

Baker's (2001) distinction can easily be connected to the four types of state ideologies that, according to Bourhis (2001), generally shape the integration and language policies of immigration societies. The ideological position of a state concerning the integration of immigrants has important consequences for their possibilities to preserve their first language (L1) and culture in the host society and to acquire the society's dominant language (L2). In a *pluralist* ideology, the state provides support for language classes and facilitates cultural activities in order to promote L1 maintenance alongside L2 proficiency. A *civic* ideology expects immigrants to adopt the values, norms, and language of the mainstream society. The state does not, however, interfere with the private values of its citizens regarding language and culture, nor does it provide any facilities for the maintenance of immigrant minority languages or culture. An *assimilationist* ideology expects a general adaptation to the mainstream society, especially aimed at accelerating linguistic and cultural shift. An *ethnicist* ideology, finally, has much in common with an assimilation ideology, but on top of it, it explicitly counteracts linguistic and cultural diversity and makes it difficult for immigrant minorities to be accepted legally and/or socially as full and equal members of the mainstream society. In a democratic society, one or a combination of these ideologies – reflecting the possible variety of a society's members' opinions – via elections can become the guiding principle for dealing with immigrant language policies. It goes without saying that majority opinions in this respect have a much better chance of becoming dominant than immigrant or minority perspectives. It also goes without saying that majority opinions are primarily located at the more assimilationist side of the continuum. It must be noted, however, that many members of minority and immigrant groups are persuaded by social and economic pressure to accept assimilationist beliefs.

Minority and Majority Languages in Education

The 1997 *Encyclopedia of Language and Education* had a separate volume on *Bilingual Education* (Cummins and Corson, 1997). In the introduction to this volume, Cummins (1997: xi) states that although a "large majority of countries throughout the world offer some form of bilingual education," bilingual education for minority groups is

> "highly controversial" because it "is accurately seen by both advocates and opponents as at least potentially a challenge and form of resistance to dominant group hegemony which is perceived to be weakened by the 'infiltration' of diverse languages into 'mainstream' societal institutions such as schools."

In Cummins and Corson (1997), bilingual education, generally speaking, is presented as a successful and still developing contribution to improving educational opportunities of immigrants and other minorities and/or creating a culturally and linguistically diverse pluralist society.

What is referred to as bilingual education, through the years actually consisted of quite a number of different approaches that in the course of time have undergone considerable changes and used a host of different designations to refer to the languages that were the focus of attention. Anthologies such as Extra and Gorter (2001) and Extra and Yağmur (2004) contain terms such as 'native language,' 'mother tongue,' 'own language,' 'vernacular language,' 'community language,' 'ancestral language,' 'heritage language,' 'language of origin,' 'nonindigenous minority language,' 'allochthonous (minority) language,' 'immigrant (minority) language,' 'ethnic minority/group language,' or 'language other than English' – all referring to different policy visions of the languages involved and at the same time "all euphemisms intended to recognize that they are not the majority language" (Kaplan and Baldauf, 1997: 21; see also Kroon, 2003).

A main distinction to be made here is between approaches in which the immigrant minority language is used in a maintenance or transitional program or any other approach as a language of instruction in a variety of school subjects on the one hand, and approaches in which the immigrant minority language is a teaching subject in its own right, within, connected to, or outside the curriculum on the other

hand. Experience shows that minority language used for instruction, although not widespread, has a much greater impact on educational arrangements than minority languages taught as a subject. Whereas teaching immigrant minority languages as a subject to immigrant minority pupils does not necessarily influence a school's regular curriculum and might even go unnoticed by the majority, using immigrant minority languages as a language of instruction clearly affects and changes the school's image and as such more easily becomes a controversial issue in public and scholarly debate.

Almost a decade after Corson and Cummins' (1997) critical but basically positive evaluation of ongoing developments in bilingual education all over the world, a negative shift in public and scholarly appreciation of including immigrant minority languages in education seems to be imminent – if it has not already happened. The main reason for this shift – often triggered by opinion leaders giving voice to assumed general feelings and fears regarding the increasingly multicultural character of society, and soon adopted by politicians and governmental authorities, formally representing these concerned citizens – seems to lie in changing evaluations and opinions regarding the long-term viability of multicultural societies (Cuperus *et al.*, 2003). The rhetoric and practice of bilingual education in the last three decades or so of the 20th century can be characterized as mainly based on pluralist or civic ideologies that favored or accepted multiculturalism and as a consequence considered multilingualism as a right or at least as a resource, and argued in favor of including immigrant and other minority languages in education. In the first decade of the 21st century, however, mainly assimilationist and sometimes ethnicist ideologies have come to the fore that reject or oppose multiculturalism and as a consequence consider multilingualism first of all as a problem and as a threat to society, and so argue in favor of reducing or abolishing immigrant minority language teaching in schools altogether. This negative shift in the appreciation of including immigrant minority languages in education more often than not has gone hand in hand with a shift in national immigration and integration policies, leading to strict, defensive, restrictive, and daunting immigration laws and regulations, and accompanying integration measures for those immigrants, refugees, and/or asylum seekers who succeed in being admitted to their country of choice. Such measures generally include the compulsory acquisition of a certain level of proficiency in the dominant language of the host country and of some knowledge of the country's history and aspects of its contemporary organization of society. Depending on the strictness of a country's immigration and integration policies, language courses and tests for so-called 'newcomers' are sometimes organized, in the country of origin or in the immigration country, e.g., before or after entry, and they can also be made compulsory for those immigrants who have already lived and worked much of their lives in the immigration country.

In such policies, the authorities' central focus is on promoting or requiring the acquisition of the dominant language of the country of immigration, which for the majority of immigrants is a second language, via an extensive and diversified offer of second language teaching methodologies. These can vary from second language courses for newly arrived immigrants giving access to regular forms of education or work, to integrated, content-based second language courses for second-generation immigrants in mainstream classrooms (see Baker, 2001 and Van den Branden, 2006). But hard-core, L2-immersion without any special provisions for the first and second generation immigrant pupils involved is still widespread. In such cases, the authorities do not attach any official value to immigrant minority languages and do not include them in regular state-funded education arrangements, and may even oppose their use and preservation. As a consequence, as a first step, maintenance and transitional forms of bilingual education are abolished, then immigrant minority language teaching as a subject is moved outside the regular curriculum and the school, and there is no effort to use immigrant minority languages as support languages for immigrant minority pupils within the regular curriculum. In this view, knowledge of the dominant majority language is perceived as decisive for being a citizen, whereas knowledge of immigrant minority languages simply does not count and is totally left to the initiative of the immigrant minorities involved.

It is remarkable to observe how easily the 'monolingual habitus' (Gogolin, 1994) that is reflected by this restrictive policy position regarding multilingualism and language teaching in the context of immigration can be turned into a 'multilingual habitus' when it comes to formulating policies concerning foreign language proficiency of the so-called European citizen, who as consequence of internationalization and globalization is expected to know, besides his or her own national language, at least two other national languages of the European Union (Block and Cameron, 2002). The same politicians who downplay the position of immigrant minority languages in forms of bilingual education, at the same time plea for establishing bilingual schools that use English as

a language of instruction instead of or alongside the national language (De Bot *et al.*, 2001). The mantra of multilingualism is permanent, only the ingredients can change.

Immunity to Error through Misidentification

K Romdenh-Romluc, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Suppose I overhear a conversation and so come to believe the fact in (1).

(1) Ernie owns a poodle.

Two simple errors I may make are these: I may be mistaken because Ernie owns a greyhound. If so, I have predicated the wrong thing of Ernie. Or I may be mistaken because it is Bert who owns the poodle. In this case I have misidentified the poodle's owner. The latter is called an error of misidentification. To say that an utterance is immune to error through misidentification (IEM) is to say that this sort of mistake has been ruled out. If I see a dog in front of me and so form the belief in (2), I cannot be wrong about *which* dog my judgment is about (although I can make other sorts of mistakes – perhaps the dog is not a highland terrier, or perhaps I am hallucinating and there is no dog).

(2) That dog is a highland terrier.

Whether or not an utterance about something is IEM depends on how the utterer is thinking about that thing and how he or she has come to know facts about it. The phenomenon interests philosophers because certain 'I'-utterances are IEM, and since many

a language of instruction instead of or alongside the national language (De Bot *et al.*, 2001). The mantra of multilingualism is permanent, only the ingredients can change.

Immunity to Error through Misidentification

K Romdenh-Romluc, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Suppose I overhear a conversation and so come to believe the fact in (1).

(1) Ernie owns a poodle.

Two simple errors I may make are these: I may be mistaken because Ernie owns a greyhound. If so, I have predicated the wrong thing of Ernie. Or I may be mistaken because it is Bert who owns the poodle. In this case I have misidentified the poodle's owner. The latter is called an error of misidentification. To say that an utterance is immune to error through misidentification (IEM) is to say that this sort of mistake has been ruled out. If I see a dog in front of me and so form the belief in (2), I cannot be wrong about *which* dog my judgment is about (although I can make other sorts of mistakes – perhaps the dog is not a highland terrier, or perhaps I am hallucinating and there is no dog).

(2) That dog is a highland terrier.

Whether or not an utterance about something is IEM depends on how the utterer is thinking about that thing and how he or she has come to know facts about it. The phenomenon interests philosophers because certain 'I'-utterances are IEM, and since many

writers take 'I'-utterances to express first-person thoughts, it seems that this fact can shed light on first-person thinking. The next section explains how someone must think about/come to know about *x* for an utterance about *x* to be IEM. In a later section, the main positions in the debate about IEM 'I'-utterances are presented.

IEM

There are different ways for an utterance to be IEM. To come to grips with the phenomenon, we first need to understand what it is for an utterance to be *open* to this kind of error (OEM). In the first example, if the poodle belongs to Bert, I make an error of misidentification when I judge (1), because I mistake Ernie for the poodle's owner. In other words, I judge that Ernie is numerically identical with the owner of the poodle, and my judgment is false, because the person who owns the poodle is Bert. Thus we can see that an error of misidentification consists in mistakenly judging that one thing is numerically identical to another, and it is primarily judgments of numerical identity, as in (3), that are OEM.

(3) The person who wrote *Crime and Punishment* is Dostoevsky.

Some subject-predicate judgments are also OEM. This is because they depend on judgments of numerical identity (Evans, 1982: 180). Suppose that I see a llama standing in a field and wearing a blue blanket and make the subject-predicate judgment in (4).

(4) My sister's llama is wearing a blue blanket.

That, in turn, depends on two further judgments. One is a perceptual-demonstrative judgment about *that* llama (the one I can see), as in (5).

(5) That llama is wearing a blue blanket.

The other is a judgment of numerical identity, as in (6).

(6) That llama is my sister's llama.

If (6) is false, in judging (4), I will misidentify the llama that is wearing a blue blanket. Hence, (4) is OEM, because it depends on (6).

Since a judgment will be OEM if it either is or depends upon a judgment of numerical identity, it follows that a judgment will be IEM if it is not of these types. There are many different kinds of judgments that are IEM. However, discussion in the literature tends to focus on IEM subject-predicate judgments. These are perceptual-demonstrative judgments – i.e., judgments that are wholly based on direct awareness of the thing the judgment is about, as in (5).

(5) That llama is wearing a blue blanket.

It is clear that (5) is IEM – I cannot be wrong about *which* llama is wearing a blue blanket (although my judgment can go wrong in other ways, e.g., if the blanket is not blue, there is no blanket, or there is even no llama). The example in (5) is IEM because I both identify the object of the judgment (the llama) and come to know that it is wearing a blue blanket on the basis of my seeing it in the field. As a result, (5) does not depend upon a judgment of numerical identity, and so the possibility of error through misidentification has been ruled out.

IEM 'I'-Utterances

Philosophers are primarily interested in IEM because some 'I'-utterances are IEM. It seems, e.g., impossible to utter the sentence in (7) and be mistaken about *which* person is in pain.

(7) I am in pain.

It is widely held that 'I'-utterances express first-person thoughts. If this is so, then the fact that some are IEM can shed light on the nature of first-person thinking, and the self. Nearly all writers accept that some 'I'-utterances are IEM (see, however, Campbell, 1999), but the source of this immunity is disputed.

What is perhaps the most influential account of IEM 'I'-utterances assimilates them to perceptual-demonstrative judgments. Those 'I'-utterances that are IEM appear to express subject-predicate judgments. When I utter (7), I seem to be saying that some object (myself) satisfies the predicate 'in pain'. We see in the first section of this article that a subject-predicate judgment will be IEM if it is wholly based on direct awareness of the thing the judgment is about. Many writers are thus led to conclude that an utterance such as (7) is IEM because it is wholly based on direct awareness of oneself – I observe myself and observe that I am in pain. These writers thereby treat 'I' as a perceptual-demonstrative comparable to terms such as 'this' and 'that' (note, however, that these terms also have uses that are not perceptual-demonstrative). But 'I' does not behave like other perceptual-demonstrative terms. I can use a term such as 'that' to refer to lots of different things; sometimes an utterance of 'that' will fail to refer to anything – e.g., if I hallucinate a llama before me, my attempts to refer to it using 'that' will fail. In contrast, it is traditionally claimed that I can only refer to myself using 'I,' and 'I' cannot fail to refer. Thus, the self-awareness that underlies 'I'-utterances that are IEM cannot be like ordinary forms of observation. First, I use a perceptual-demonstrative term such as 'that' to refer to something I currently see. 'That' can be used to refer to lots of different things,

because I can see many entities. If 'I' is a perceptual-demonstrative that can be used to refer only to oneself, it follows that its use must be based on awareness one can have only of oneself. Second, perceptual-demonstratives can fail to refer because we can have illusory experiences, where we seem to perceive an object that is not in fact there. Since 'I' cannot fail to refer, the awareness that underlies its use must not allow for the possibility of complete hallucination in this way.

Various objections to the perceptual-demonstrative account of IEM 'I'-utterances have been raised. Anscombe (1981) objected that the only sort of awareness that could fit the bill would be introspection of a nonphysical self. This claim creates trouble for the view that IEM 'I'-utterances should be treated as perceptual-demonstrative judgments because theorists these days take the self to be a physical entity. A further problem was raised by Shoemaker (1968). On the perceptual-demonstrative view, I make an utterance like (9) on the basis of direct awareness of the thing the judgment is about – myself. However, Shoemaker argued that observing a self and noticing that it is in pain only allows me to judge (8) in the same way that observing a llama and noticing that it is wearing a blue blanket allows me to judge (5).

(8) That self is in pain.

(5) That llama is wearing a blue blanket.

But (8) is clearly not equivalent to (7). First-person thoughts have a special role in bringing about action (*see* **Essential Indexical**). I may, e.g., see myself reflected in a shop window, notice that the person I see reflected is standing in the way of the street sweeper, and so judge (9).

(9) That person is obstructing the street sweeper.

But even if I am cooperative, I will not move out of the way unless I believe (10).

(10) *I* am obstructing the street sweeper.

If observing a self and noticing that it is in pain allows me only to judge (8), to judge (7), I will have to make the judgment of numerical identity (11).

(8) That self is in pain.

(7) I am in pain.

(11) I am that self.

It is unclear on what basis I could judge (11). Moreover, as we have seen, if a subject-predicate judgment depends upon a judgment of numerical identity, then it is OEM. It follows that if I judge (7) on the basis of (8) and (11), then (7) will be OEM. But (7) is IEM; thus, I cannot judge (7) on the basis of (8) and (11). Shoemaker concluded, therefore, that IEM 'I'-utterances cannot be based on self-observation.

Evans (1982) attempted to give a perceptual-demonstrative account of IEM 'I'-utterances that did not fall prey to these objections. We have seen that 'I' differs from other perceptual-demonstrative terms in that I can refer only to myself using 'I', and 'I' cannot fail to refer. It follows that IEM 'I'-utterances must be based on a form of awareness that one can have only of oneself and that does not allow for hallucination in the same way as a sense like vision, where I can seem to see an object that is not there. Evans suggested that proprioception – the 'inner' sense of one's body, its temperature, limb position, movements, etc. – satisfies both of these conditions. Indeed, it gives rise to 'I'-utterances that are seemingly IEM. If, e.g., I feel that my legs are crossed and utter (12), I surely cannot be wrong about which person has their legs crossed.

(12) I have my legs crossed.

Evans held that all IEM 'I'-utterances are based upon proprioceptive experience of one's body.

Anscombe objected to the perceptual-demonstrative account of IEM 'I'-utterances, because it seemed that only introspection of a nonphysical self could satisfy the relevant conditions. Evans's account silenced this objection, because proprioception is awareness of one's body. It could also deal with the worry raised by Shoemaker. Shoemaker claimed that observation of a self could license only a judgment such as (8), rather than (7).

(8) That self is in pain.

(7) I am in pain.

Judgments (7) and (8) are not equivalent, because they have different implications for action. One might think that Shoemaker could make the same objection to Evans's account: proprioceptive experience allows me only to judge, e.g., (13) and not the first-person judgment (12).

(13) That body has its legs crossed.

(12) I have my legs crossed.

However, proprioceptive experience allows us to act unreflectively on the information given in that experience. Suppose that I feel a mosquito crawling on my arm; I can immediately slap my arm without thinking about doing so. In particular, I do not need to identify the arm I can feel the mosquito crawling along as *my* arm. The way in which proprioceptive awareness has an immediate bearing on my actions suggests that it is awareness that is distinctively first-personal. It follows that it can license a first-person judgment such as (12), not merely a judgment such as (13). Thus,

Evans's account does not fall prey to Shoemaker's objection.

Evans's account, however, is not free from problems. It is perhaps conceivable that I could have proprioceptive experience of another's body if my brain were appropriately 'wired' to their limbs. In such a case I might judge (14).

(14) I have an itch in my left foot.

But since my proprioceptive experience comes from their body, not mine, in judging (14), I misidentify the person whose left foot is itchy. Examples such as this are famously taken to show that judgments based on proprioceptive awareness of one's body are not IEM.

Wittgenstein, who is credited with first noticing that certain 'I'-utterances are IEM, gives a radically different analysis of such utterances. To understand his account, we need to distinguish between utterances and judgments. I have so far spoken as if they are interchangeable. In many cases this is acceptable, because utterances are often used to express judgments. Suppose I am asked a question in class and answer (15).

(15) The capital of England is London.

My utterance expresses a judgment that London is the capital of England – by uttering (15), I express my commitment to the existence of a particular country, the existence of a particular city, and the obtaining of a particular relation between them. However, not all utterances express judgments. Suppose that I utter (16) as the punch line of a joke.

(16) John's donkey is drunk.

Unlike (15), (16) does not express a judgment – I am not committed to the existence of John or his donkey. Since an error of misidentification consists in mistakenly judging that one thing is numerically identical to another, if I make an utterance that expresses no judgment, my utterance will be IEM. When I utter (16), I am not committing myself to the existence of some particular donkey, which I believe to be drunk. It thus makes no sense to suppose that I could misidentify the donkey in question.

Wittgenstein (1953) accounted for the IEM status of certain 'I'-utterances in this way. He argued that some present-tense 'I'-utterances that involve psychological predicates, such as (17), cannot be understood as expressing judgments.

(17) I feel dazed.

Instead, we should think of them as expressing one's psychological states in much the same way that groaning sometimes expresses pain. 'I'-utterances of this sort are IEM; they have this status, according to Wittgenstein, because they do not express judgments. A consequence of this view is that 'I,' as it is used in these utterances, does not refer to anything. It makes no sense to talk of a groan as having a referent. Since utterances like (17) express psychological states in the same kind of way that groaning sometimes expresses pain, 'I' as it is used in (17) does not refer to anything. Most have dismissed Wittgenstein's 'no-reference thesis,' as this view is called. It is also unclear how IEM 'I'-utterances involving *physical* predicates (assuming that there are such utterances) should be treated on the Wittgenstein picture. Suppose a particular bodily sensation prompts me to utter (12).

(12) I have my legs crossed.

It is unclear how (12) could be treated as expressing a state in the same way that groaning can be understood as expressing pain.

Impairments of Proper and Common Names

C Semenza, University of Trieste, Trieste, Italy

© 2006 Elsevier Ltd. All rights reserved.

The distinction between common and proper names is a fundamental one in lexical semantics. The two categories, in fact, are distinguishable from one another since they have a different type of reference. This fact has been shown to impinge on the kind of processing each category undergoes. Neuropsychological research in the past 20 years has indeed uncovered a series of phenomena that critically contribute to the understanding of how proper names are processed in the brain with respect to common names. These findings could be interpreted in light of past and current philosophical and linguistic theories on the nature of proper and common names, that, in turn, received empirical support. Thus, the role of a very important dimension, that of the amount of 'sense' in Frege's (1892) terms, was highlighted, and it became possible to distinguish semantics referring to individuals from general semantics.

Relevant philosophical and linguistic theories can be summarized as follows. Proper names are thought to relate to their reference in a 'token' (individual) as opposed to 'type' (categorical) fashion, which is the case for common nouns. In other words, while proper names refer to individual entities, common nouns refer to categories of items. According to philosophers like Frege (1892) or, more recently, Kripke (1980), proper names are pure referring expressions, in that they carry little if any sense or connotation beyond that of the reference. In other words, proper names do not entail any description of the entity they designate. Changing basic features and properties over time does not change the proper name of a given single entity. Another way of expressing this fact is to tell that proper names have an arbitrary relation with their reference. As Semenza *et al.* (1998) have observed, a name designating a category applies to a set of attributes that overlap or interact with each other via high-probability connections. In the set of attributes labeled by a proper name, instead, attributes combine together incidentally, being related to each other only by virtue of belonging to entities that are unique. This distinction resembles closely that universally made between semantic and episodic memory mechanisms, but with an important difference: the mechanisms in question are more peripheral and operate at the lexical level.

In neuropsychology, cases were discovered whereby, as a result of a brain lesion, patients were affected by selective anomia for proper names, with normal retrieval of common names. Cases of the reverse pattern – proper name selective sparing – have also been reported.

Anomia for proper names, in general, affects retrieval in all testing conditions and comes in different varieties, the most common (so-called 'pure proper name anomias') being those originating with a deficit at a postsemantic level (i.e., failure to access the name's phonological form from an intact semantic system, e.g., Semenza and Zettin, 1988, 1989; Lucchelli and De Renzi, 1992; Hittmair-Delazer *et al.*, 1994). The phonological level itself seems to be spared in these patients, since they maintain the ability to read aloud irregularly spelled proper names. This type of anomia comes in two different subtypes: one concerns all proper names, while the other is limited to people's names only. It is still unclear whether proper names other than people's ones are easier than the latter or rather have particular properties that may help in circumventing the deficit. Most of these patients seem little if not at all sensitive to phonemic as well as semantic cueing, but a combination of both types of cue has been shown to yield some improvement. Cases, however, have been reported of patients showing a significant improvement when aided with a phonological cue (e.g., Lucchelli and De Renzi, 1992; Otsuka *et al.,* 2005). Other cases have been shown, instead, to derive from a problem within the semantic system (e.g., Miceli *et al.*, 2000), where information about individual people seems to be selectively lost with respect to information about other entities, or from the isolation of information on individual entities from both the general semantic system and the output lexicon (Van der Linden *et al.,* 1995; Semenza *et al.,* 1998). Thus, while some patients cannot retrieve the name but have no problem showing they know everything else about the individual, other less frequently observed patients seem to be selectively impaired in the semantic store containing all the information about that individual, including the corresponding name. In 'isolation' cases the information was available but could only be triggered by providing the proper name itself. A last variety, only very recently described, is that of 'prosopanomia' (Semenza *et al.,* 2003), a face-specific optic aphasia, where patients cannot retrieve the names of people by just looking at their faces but they can do so on definition. They have no trouble recognizing the face, but like optic aphasics, they seem instead unable to retrieve enough semantic information from the visual stimulus (in this case, specifically, only from faces) to activate the name.

Anomias for proper names arising at the retrieval level are also important for their concomitant symptoms. While, at least in the purest cases, they seem to come as the only reported symptom, careful neuropsychological assessment systematically uncovers a revealing constellation of associated deficits. Semenza and Zettin (1989) first showed that their proper name anomic could not retrieve a member of an arbitrarily related word pair given the other. The same patient and similar ones could not retrieve 'token' information arbitrarily connected with other information, such as known phone numbers of people, titles of wordless pieces of music, dates of known events, etc. This finding provides support for theories of proper names as pure referring expressions, whose link with the entity they represent is arbitrary, nondescriptive (i.e., unlike with common nouns, not implying attributes), and thus devoid of sense.

Cases of selective sparing of proper names are more complicated than proper name anomias and do not seem to tell a straightforward story. Two main factors contribute to this state of uncertainty and, consequently, to the difficulty in identifying the nature of the functional deficit. First, in general, sparing of proper names has been found in otherwise very severely affected patients. This fact has seriously hampered the possibility of testing the patients in the desirable level of detail. Second, the conditions in which proper names are selectively spared appears to differ widely from case to case; in fact, unlike in cases of the most common (postsemantic) proper name anomia, which all look rather similar, no single reported case of proper name sparing closely resembles any of the others. For instance, the first such case ever observed (McKenna and Warrington, 1978) concerned only the names of nations. In another case, reported by Cipolotti *et al.* (1993), the patient could be tested only in writing, where he could retrieve only names of countries and famous people. In the case reported by Semenza and Sgaramella (1993), the patient could not retrieve any name, and selective preservation of proper names emerged only in the middle of a gibberish jargon, and, more clearly, after phonemic cueing in picture naming. In contrast, Cipolotti's (2000) patient showed proper name superiority just for countries and only in oral naming and reading aloud. In another case (Schmidt *et al.*, 2004), preserved sparing was shown only in the written condition in a patient whose articulation was totally impaired. This patient showed semantic knowledge about items whose (common) name he could not retrieve and never committed paragraphias; these facts led the authors to suggest that the functional deficit could be located in accessing, from an intact semantic level, an intact orthographic lexicon. Unfortunately, the patient's extremely severe articulation problems prevented assessing the status of his phonological lexicon. In the case described by Lyons *et al.* (2002), the patients not only missed common nouns but also the correspondent semantic information: in contrast, the patient showed a normal ability to retrieve people's names and the corresponding biographical information.

With one exception, none of the patients with proper name sparing described in the literature truly mirrors reported cases of anomia for proper names. Because of the severity of the cases, only limited testing results are available for any one patient, so it has been very difficult to locate the deficit at a particular processing stage.

This review thus shows that a convincing double dissociation in the processing of proper and common names, the clearest evidence for separate systems, has not been described at all processing stages. The only exception is indeed constituted by two cases, the proper name anomia studied by Miceli *et al.* (2000) and the proper name selective sparing reported by Lyons *et al.* (2002). These cases really mirror each other, insofar the former, as reported above, missed the knowledge of the semantics of individual entities while preserving knowledge of categorical entities, while the latter, instead, showed exactly the reverse pattern.

Strangely, the most frequent pattern of proper name anomia (i.e., where the defect has been located at the postsemantic lexical activation level) is not clearly mirrored by any case of proper name sparing. Before Miceli *et al.* (2000) and Lyons *et al.* (2002) had described their patients, the lack of a double dissociation could be taken as meaning that the processing of the two categories follows the same path. Semenza (1997), however, warned against this last interpretation by pointing out that the patients reported in Semenza and Zettin (1988, 1989) could retrieve virtually all items in their presumed premorbid vocabulary, and were well within, if not superior to, normal level in the retrieval of common names. They could indeed retrieve very difficult abstract names and correctly name in a minute a high number of items from odd common name categories. In contrast, they were profoundly impaired with proper names to the point that they could retrieve only their own name and that of a few family members. The fact that they were unable to retrieve the names of people they had known all their lives and met almost every day indicates that this dissociation cannot be determined by low frequency or familiarity of such items; rather, it

suggests that proper names have a separate processing pathway.

The problem remains of why, with about two dozen cases of anomia for proper names described in literature, their selective sparing is still so hard to find. One possible explanation is that the retrieval of proper names is simply more difficult than the retrieval of common nouns. This position is widely held and anecdotally supported, but experimental confirmation has been difficult to obtain (Cohen and Burke, 1993). In fact, the main methods used in the past to demonstrate proper names' relative difficulty with respect to common names proved to be largely inadequate. It is indeed very hard if not impossible to match for perceptual difficulty visual stimuli consisting of pictures of faces (for proper names) and pictures of objects (for common names). Diary studies, instead, collecting participants' naming failures in a given period of time, were hampered by the obvious fact that one often hardly notices missing a common name, while missing a proper name may cause serious embarrassment.

Thus, the best available evidence for proper names being indeed more difficult to process rests mainly on two types of relatively recent observations. One concerns the so called 'baker–Baker' paradox: it is easier to learn that a face belongs to a baker than it is to learn that the same face belongs to a Mr Baker (McWeeny *et al.,* 1987; Cohen, 1990). This effect cannot be attributed to differences in the phonological form or frequency of occurrence of occupations versus proper names. Another methodology – repetition of supraspan lists of words – shows a significantly weaker priority effect when the list is composed of proper names than when it is composed of common nouns matched to proper names for frequency, length and phonological complexity (Hittmair-Delazer *et al.,* 1994; Semenza *et al.*, 1996; Pelamatti *et al.*, 2003). This effect widens with age and exposure to high altitude and comes to an extreme with Alzheimer's disease.

Proper name recognition has also been studied in neuropsychology. A selective deficit in proper name recognition *vis-à-vis* sparing of the comprehension of common names was first reported by Verstichel *et al.* (1996) in a patient who showed the same dissociation in output. Sparing in recognition of proper names relative to common ones has also been reported (Saffran *et al.,* 1980; Van Lanker and Klein, 1990), generally after major damage to the left hemisphere.

Once established that proper and common names follow different functional pathways, an important and debated issue concerns localization of proper name processing in the brain. Reported investigations so far employed lateralization techniques, ERPs (Evoked Response Potentials), neuroimaging, and classic clinical–anatomical correlation.

Ohnesorge and Van Lanker (2001), reviewing findings via lateralization techniques on proper name recognition, came to the following conclusions: greater accuracy is found in the right visual field for both common proper names; famous proper names are overall more accurately recognized; no field difference exists for famous proper names in categorization tasks and for more familiar items. The authors suggested that both hemispheres can process famous proper names and that the right hemisphere contributes to personal name recognition because it may be specialized for items of 'personal relevance.'

An ERP study carried out by Proverbio *et al.* (2001) revealed that tacit retrieval of a proper name phonological form is reflected in a strong activation of left anterior temporal and left centrofrontal areas, while the same task shows greater involvement of occipitotemporal areas with common names.

Neuroimaging studies (Damasio *et al.,* 1996; Gorno Tempini *et al.,* 1998; Rotschtein *et al.,* 2005) seem to indicate a critical role of the left temporal pole in naming of faces and that proper name categorization depends on the left–anterior middle–temporal region.

Finally, the anatomoclinical correlation method (Semenza *et al.,* 1995; Yasuda *et al.,* 2000) allowed researchers to reach the following conclusions: a) in proper name anomias, the left temporal lobe is often damaged; b) several cases are determined by left-sided lesions clearly outside the temporal lobe, including the basal ganglia, the thalamus, and the occipital lobe; c) the left temporal lobe is most often damaged also in selective sparing of proper names; and d) at least one case of selective sparing of proper names followed a lesion in the left temporal pole. The most recent review (Yasuda *et al.,* 2000) thus concluded that various aspects of proper name retrieval may be sustained by different structures differently participating in a complex network: existing speculations about the specific role of each of these structures remains at present unwarranted.

In summary, localization studies lead to the suggestion that a dedicated module dealing with proper name retrieval probably exists, but it is either subject to great interindividual variation or it is distributed throughout a large portion of the left hemisphere.

Imperatives

J van der Auwera, University of Antwerp, Wilrijk, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Imperatives can be defined as constructions of grammar that typically express a state of affairs as desirable by the speaker and that furthermore appeal to the hearer(s) to fulfill the desire. Thus, sentence (1) is an imperative. It has the meaning just described, and the construction type is defined in terms of grammar, especially syntax (the clause lacks a subject and it starts with a finite verb) and, less so, morphology (the bare form of the verb is highly polyfunctional).

(1) go home now

Sentence (2) expresses the same meaning in Polish; in this language, there is unique imperative morphology.

(2) idź teraz do domu
go.IMP.IMPERF.2.SING now to house
'go home now!'

Sentence (3) expresses more or less the same meaning, but this is not so much due to grammar as to the use of lexical items, most particularly, the volitional predicate *want*.

(3) I want you to go home now

Sentence (4) is not an imperative either.

(4) if only you would go home now

Sentence (4) does express a desire by the speaker, but it does not encode an appeal to the hearer to go home. The appeal is not part of the semantics of the *if only* construction, even though it could convey it as a Gricean implicature.

Next to imperative constructions that can be called typical, we can find atypical ones. In a permission, the speaker's desire is less salient than that of hearer, to the extent that even the speaker can say that he or she does not want the state of affairs.

(5) I don't want you to go home now, but go anyway

But even then, there is still at least the speaker's desire to gratify the hearer's wish. In an advice or in an instruction, however, the component of the speaker's desire is even less relevant and in the pluperfect imperative of Dutch (Haeseryn *et al.*, 1997: 1634), there is a desire, but it is past and unfulfillable.

(6) if you want to go to the station, take bus 66

(7) had je mond maar gehouden!
had your mouth but kept
'you should have kept your mouth shut!'

In the narrative imperative of Russian (Fortuin, 2000: 134), finally, there is no desire whatsoever.

(8) stala ja sosedok rassprašivat' a oni mne
started I neighbors interrogate and they me
vsë i rasskaži
all and tell.IMP.PERF.2.SING
'I started to interrogate the neighbors . . . and they just told me everything'

The polyfunctionality sketched in the previous examples can be dealt with in two ways. In a monosemantic approach, one attempts to define a meaning that is common to all relevant uses. Because of the multiplicity of uses, this one meaning will be relatively abstract (see, e.g., Davies, 1987: 145). In a polysemantic approach, it suffices to describe the relevant uses as being related to one another, thus allowing them to constitute a polysemantic network. In both approaches, one could also decide that a certain use is not in fact an instantiation of the one general meaning or a partner in the polysemy network and that it, rather, illustrates a case of homonymy. The Russian narrative imperative is a case in point; see Fortuin (2001: 134–161) for a discussion of the homonymy account in contrast to monosemantic and polysemantic accounts.

Similar polyfunctionality issues arise when we demarcate imperatives from optatives, subjunctives, or irrealis constructions. In modern Persian (Western Farsi), the subjunctive has a variety of uses, both in dependent and in independent clauses. In independent clauses, it can express desire and exhortation to first, second, and third persons. The Persian imperative has the typical meaning previously sketched. In the second-person singular, it is formally different from the subjunctive, but not in the second-person plural (see Table 1). We could thus conclude that Persian only has an imperative second-person singular and that the second-person plural uses are taken care of by the subjunctive form or perhaps a

Table 1 Subjunctive and imperative paradigms in modern Persian (Western Farsi)

		Subjunctive		*Imperative*	
SG	1	*be-xar-am*	'that I buy'		
	2	*be-xar-i*	'that you buy'	*be-xar*	'buy'
	3	*be-xar-ad/e*	'that he/she buys'		
PL	1	*be-xar-im*	'that we buy'		
	2	*be-xar-id/in*	'that you buy'	*be-xar-id/in*	'buy'
	3	*be-xar-and/an*	'that they buy'

Table 3 Una imperatives

Example		*Imperative paradigm*
buk-num	'let me sit down right now!'	Immediate imperative
buk-u-num	'let me sit down!'	Near deferred imperative
buk-wama-nun	'let me sit down in a while!'	Regular deferred imperative
buk-wa-nun	'let me sit down later on!'	Remote deferred imperative
bu-ra-nun	'let me sit down continually!'	Continuous imperative

Source: Louwerse (1988: 36–37).

more general subjunctive-imperative. Traditionally, however, Persian is credited with both a singular and a plural imperative, and we just remark that the imperative plural is identical to the subjunctive second-person plural. In cases in which there is no form that is dedicated to the typical function of imperatives, we could, of course, say that the language lacks an imperative, as in the Malayo-Polynesian language Manam, for which Lichtenberk (1983: 187–191) mentions an irrealis form that has as one of its uses something considered typical for imperatives. Another example is the Australian language Nunggubuyu, in which a form can have both future and imperative readings (Heath, 1984: 343–344).

A point of controversy is whether imperatives are exclusively second person. One can embrace a wide view, in which constructions such as English (9), Russian (10), and Korean (11) (Sohn, 1999: 274) are also considered to be imperatives (e.g., Birjulin and Xrakovskij, 2001).

(9) let's go now!

(10) pust' oni sejčas idut
let they now go.IND.PRS.IMPERF.3.PL
'let them go now!'

(11) nay ka ka-ca
I NOM go-IMP
'let me go!'

Alternatively, and more commonly perhaps, constructions such as (9) to (11) are given labels such as hortative, jussive, propositive, or injunctive (e.g., Ammann and van der Auwera, 2004). The difference between the two approaches may be only a terminological one, but the issue can again be related to degrees of prototypicality. The prototypical imperative was claimed to involve an appeal to the hearer to fulfill a desire of the speaker. In the most typical imperative, the hearer is him- or herself in control of the desired state of affairs and can thus fulfill the desire in a straightforward way. In (9), (10), and (11), the situation is a little special. In (9), there is an appeal to both the hearer and the speaker. In (10), the appeal is still directed toward the hearer, but the latter is not in control. The hearer is only called on to create the circumstances favorable to the third party's action, but it is the latter that has to act. In (11), the speaker talks to him- or herself; he or she is both the speaker and the hearer.

Just as languages differ as to whether they have grammaticalized more or less dedicated second-person imperatives, they also differ as to whether they have grammaticalized non-second-person constructions such as (9)–(11) (see van der Auwera *et al.*, 2004). Both *let's* and *pust'* transparently derive from a 'let' verb and can be considered particles now, the Russian one more clearly so than the English one; but, whereas *let's* is used only for the first-person plural, Russian *pust'* is only used for the third persons. Thus, neither Russian nor English has a homogeneous full person paradigm.

This can be contrasted with a paradigm such as Table 2, the immediate imperative of the Papuan language Una. The high degree of homogeneity is evident: For each slot, there is a stem followed by a person-number suffix. The regularity can also be illustrated by the fact that Una has no fewer than five imperative paradigms. Table 3 illustrates the first-person singular in each of the paradigms.

The Una paradigms also illustrate that imperatives can exhibit considerable morphological complexity. In languages with a small paradigm, however, the striking feature is, rather, the morphological simplicity, especially of the second-person singular, which is often just a bare stem or root of the verb or even a shortened form of it. Consider the Uralic language Udmurt. Its second-person singular imperative is normally expressed by a stem, but when the stem ends in an *-ï* that is preceded by a single consonant, this *-ï* is lost and the imperative is thus a simplified stem (Csúcs, 1998: 289)

(12a) vetlï
go.IMP.2.SING
'go!'

(12b) gïr
plough.IMP.2.SING
'plough!'

The negation of the imperative is often called prohibitive or, less often, vetative. One reason for giving it a special label is that prohibitives are frequently not compositionally derivable from positive imperatives. Consider the Australian language Djingili. Imperatives are marked with the suffix *-mi* and prohibitives by *-ji*, and this *-ji* is different from the normal indicative negation, the adverbial *angjkula* (Pensalfini, 2003: 101, 230).

(13a) dunjumi-ji, mankiya-mi
poke-PROH sit-IMP
'don't poke me, sit still!'

(13b) angjkula langkaj-nya-ju ngarru
NEG hear-SING-do 1.SING.ACC
'you're not listening to me!'

Other types are shown in (14)–(15). In the Spanish sentences in (14), we get the ordinary indicative negative marker, but it combines with a subjunctive rather than an imperative. In the Homeric Greek example in (15a) (*Iliad* 1.32), the prohibitive uses the imperative verb and *mê*, not the indicative negative marker *ou*, as in (15b) (*Iliad* 1.24).

(14a) canta
sing.IMP.2.SING
'sing!'

(14b) no cantes
NEG sing.SBJ.PRS.2.SING
'don't sing!'

(15a) mê m' erethize
NEG me provoke.IMP.PRES.2.SING
'do not provoke me!'

(15b) all' ouk Atreīdêi Agamemnoni
but NEG Atreidês. Agamemnon.
DAT.SING DAT.SING
hêndane thûmoi
please.IND.IMP.3.SING soul.DAT.SING
'but the thing did not please the heart of Agamemnon, the son of Atreus'

As the English translations in (15) show, the English prohibitive uses the same verb as in the imperative and the same negation as in the indicative.

Implicature

J Meibauer, Universität Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

The Basic Notions

The term '*implicature*' goes back to the philosopher Paul Grice, as laid down in his seminal article 'Logic and Conversation' (Grice, 1989), which is the published version of a part of his William James lectures held in 1967 at Harvard University (*see* **Grice, Herbert Paul (1913–1988)**). In Grice's approach, both 'what is implicated' and 'what is said' are part of speaker meaning. 'What is said' is that part of meaning that is determined by truth-conditional semantics, while 'what is implicated' is that part of meaning that cannot be captured by truth conditions and therefore belongs to pragmatics. Several types of implicature are distinguished. Figure 1 shows the Gricean typology of speaker meaning (cf. Levinson, 1983: 131).

The most widely accepted type of implicature is the *conversational implicature*. According to Grice, it comes in two ways, generalized conversational implicature (GCI) and particularized conversational implicature (PCI). The following example from Levinson (2000: 16–17) illustrates this distinction:

Context, 1 Speaker A: What time is it?
Speaker B: Some of the guests are already leaving.
PCI: 'It must be late.'
GCI: 'Not all of the guests are already leaving.'

Context, 2 Speaker A: Where's John?
Speaker B: Some of the guests are already leaving.
PCI: 'Perhaps John has already left.'
GCI: 'Not all of the guests are already leaving.'

Because the implicature ('. . . not all . . .') triggered by *some* arises in both contexts, it is relatively context-independent. Relative context-independence is the most prominent property of GCIs. In addition, GCIs are normally, or even consistently, associated with certain linguistic forms. For example, if someone utters *Peter is meeting a woman this evening* it is, because of the indefinite article, standardly implicated that the woman is not his wife, close relative, etc. (cf. Grice, 1989: 37; Hawkins, 1991). In contrast to GCIs, PCIs are highly context-dependent, and they are not consistently associated with any linguistic form.

Figure 1 Gricean typology of speaker meaning.

The distinction between conversational implicatures and *conventional implicatures* draws on the observation that in coordinations like *Anna is rich but she is happy*, the truth conditions are just the truth conditions of the coordination *Anna is rich and she is happy*, with the exception of the contrastive meaning of *but*. This meaning is not truth-functional, and it is not context-dependent either; hence, there is some motivation for assuming the category of conventional implicature.

Note that there may be further types of implicature, e.g., implicatures of politeness or style that are neither conventional nor conversational (cf. Leech, 1983; Brown and Levinson, 1987).

Conversational implicatures come about by the *exploitation* (apparent flouting) or *observation* of the *cooperative principle* (CP) and a set of maxims (Grice, 1989) (*see* **Cooperative Principle; Maxims and Flouting**):

Cooperative Principle
Make your conversational contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged.

Maxim of Quantity
1. Make your contribution as informative as is required (for the current purposes of exchange).
2. Do not make your contribution more informative than is required.

Maxim of Quality
Try to make your contribution one that is true.
1. Do not say what you believe to be false.
2. Do not say that for which you lack adequate evidence.

Maxim of Relevance
Be relevant.

Maxim of Manner
Be perspicuous.
1. Avoid obscurity of expression.
2. Avoid ambiguity.
3. Be brief (avoid unnecessary prolixity).
4. Be orderly.

These maxims and submaxims are conceived as rules of rational behavior, not as ethical norms. They figure prominently in the derivation of an implicature.

The basic idea of such a derivation is best illustrated with a simple dialogue. Imagine that I ask my colleague *Is Markus there?* and she answers *There is a pink Porsche behind the library building*. Understood literally, such an answer does not make any sense. However, as I assume that my colleague is cooperative, and remembering that Markus drives a pink Porsche, I can figure out that Markus is in the library. In working out this information, I have made use of the assumption that my colleague's answer has been relevant with regard to my question. Thus, conversational implicatures display the property of *calculability*. A general scheme for the working out of a conversational implicature is given by Grice (1989: 30–31):

> A man who, by (in, when) saying (or making as if to say) that *p* has implicated that *q*, may be said to have conversationally implicated that *q*, provided that (1) he is to be presumed to be observing the conversational maxims, or at least the Cooperative Principle; (2) the supposition that he is aware that, or thinks that, *q* is required in order to make his saying or making as if to say *p* (or doing so in *those* terms) consistent with this presumption; and (3) the speaker thinks (and would expect the hearer to think that the speaker thinks) that it is within the competence of the hearer to work out, or grasp intuitively, that the supposition in (2) is required.

Table 1 lists some of the most typical cases covered by the CP and the maxims. Examples for each case are given below the table. For further classical examples, see Grice (1989) and Levinson (1983). In what follows, '+>' stands for 'implicates conversationally':

(1) War is war. +> 'There is nothing one can do about it.'

(2) Some men were drunk. +> 'Not all of them were drunk.'

(3a) He is a fine friend. +> 'He is not a fine friend.'
(3b) You are the cream in my coffee. +> 'You are my best friend.'

(4) There is life on Mars. +> 'Speaker believes that there is life on Mars.'

(5) Speaker A: I'm out of petrol.
Speaker B: There is a garage round the corner.
+> 'The garage is open.'

(6) Speaker A: Look, that old spinster over there!
Speaker B: Nice weather today, isn't it? +> 'No comment.'

(7) She produced a series of noises that resembled "Sì, mi chiamano Mimi". +> 'Her singing was a complete disaster.'

(8) Anna went to the shop and bought jeans. +> 'She bought the jeans in the shop.'

Table 1 Typical cases of implicature

Maxims	*Exploitation*	*Observation*
Quantity	Tautology (1)	Scalar implicature (2)
Quality	Irony, metaphor, sarcasm (3)	Belief implicature in assertions (4)
Relevance	Implicatures due to thematic switch (5)	Bridging (6)
Manner	Implicatures due to obscurity, etc. (7)	Conjunction buttressing (8)

For further illustration of the exploitation/observation dichotomy, look at (1) and (8). As to (1), tautological utterances are always true, which amounts to their being fundamentally uninformative. There is no situation where a speaker wants to tell someone that something is identical with itself. Thus, it seems that the utterer of (1) has violated the first maxim of Quality. Gricean reasoning then leads the hearer to the insight that this violation was only apparent (cf. Autenrieth, 1997). In (8), we have a simple conjunction of two sentences. If the meaning of *and* were to be the same as the meaning of the logical operator, it could not be explained that there is an additional meaning 'and then.' Grice's view is that we may identify the semantic meaning of *and* with the pure connecting operation known from logic as long as we are able to derive the additional meaning from the maxims. The observation of the fourth maxim of Manner, "Be orderly!", will do this job (cf. Posner, 1980). Both observation and exploitation are in line with the general pattern for working out an implicature.

Besides the property of calculability, conversational implicatures display the properties of variability and cancellability. *Variability* means that there are contexts where the speaker utters the same utterance, but the respective implicature does not arise. Thus, the implicature is dependent on the specific context in which it arises. (This does not exclude the notion of relative context-independency in the case of GCIs.) *Cancellability* (or defeasibility) means that it is possible to withdraw an implicature within the situation of utterance without any contradiction. For example, it is possible to utter *Some men were drunk, indeed all*. Reversely, conversational implicatures should be *reinforceable*, as Sadock (1978) proposed. Thus, it is possible to conjoin the content of an implicature with the utterance that triggers that implicature, as in *Some of the girls were reading books but not all*.

Conventional implicatures are neither calculable, nor variable, nor cancellable. However, they are said to be detachable, i.e., if the elements that trigger them are replaced, the respective implicature does not arise.

By contrast, conversational implicatures are *non-detachable*, i.e., if there is an expression X′ that shares meaning with expression X that triggers the implicature, the same implicature should arise. For example, if *She is very beautiful* gives rise to an ironical implicature, then *She is a real beauty* should have the same effect (Sadock, 1978: 287). (An obvious exception to this are Manner implicatures.)

For further illustration, consider focus particles like *even*. An utterance such as *Even JOHN drives a Porsche* has the same truth conditions as the corresponding utterance without the focus particle, i.e., *John drives a Porsche*. The additional meaning of the type 'John is the least likely to drive a Porsche,' being related to a contextually given set of other individuals (e.g., Gustav, Bettina, Markus . . .), may be considered as a conventional implicature (cf. König, 1991), because this meaning appears to be neither truth-conditional nor context-dependent. Moreover, if *even* is replaced by another focus particle, the respective implicature is not triggered. However, if the conventional implicature is bound to the specific lexical item *even*, and for this reason is detachable, then the implicature seems to be part of the literal meaning of this lexical item. Therefore, it is difficult to distinguish between conventional implicatures on the one hand and entailments (belonging to the 'what is said') on the other hand. For this and other reasons, some researchers do not accept that there is a category of conventional implicature (cf. Bach, 1999; for a logical approach, see Potts, 2005).

Beyond Grice

The reception of the Gricean framework has been largely dominated by the wish to develop a more systematic architecture of maxims. Moreover, the Cooperative Principle has been on trial, as other aspects (e.g., logical, anthropological, cognitive, etc.) became more attractive. The prevailing tendency has been to reduce the set of maxims proposed by Grice. Three major reductive approaches have been developed: (a) the tri-heuristic approach by Levinson (2000), (b) the dual principle approach by Horn (1984), and (c) the monoprincipled approach by Sperber and Wilson (1995) and Carston (2002). These approaches are outlined in the following sections. It should be mentioned, however, that there are other important approaches that elaborate on the Gricean framework, e.g., Gazdar (1979) or Atlas (2005), as well as radical criticisms such as Davis (1998). For useful surveys, see Levinson (1983: Ch. 3) and Rolf (1994).

Presumptive Meanings: Levinson's Theory of Generalized Conversational Implicature

Levinson develops his revision of Grice's maxims from three heuristics that follow from the anthropological need to overcome the "fundamental bottleneck in the efficiency of human communication, occasioned no doubt by absolute physiological constraints on the articulators" (Levinson, 2000: 28). Accordingly, Grice's rationalistic CP plays no role. The heuristics are (Levinson, 2000: 31–33):

Levinson's Heuristics
Heuristic 1: What isn't said, isn't.
Heuristic 2: What is simply described, is stereotypically exemplified.
Heuristic 3: What's said in an abnormal way, isn't normal; or Marked message indicates marked situation.

Heuristics 1 corresponds to Levinson's Q-principle (see maxim of Quantity 1 in Grice's framework), Heuristics 2 to Levinson's I-principle (Grice's maxim of Quantity 2), and Heuristics 3 to Levinson's M-principle (Grice's maxim of Manner 1 and 3). These three principles are said to derive GCIs. For the correspondences to Grice, and a typical example, see Table 2.

Where inconsistent implicatures arise, they are "systematically resolved by an ordered set of priorities" (Levinson, 2000: 39), among them Q > M > I, where '>' is understood as 'defeats inconsistency.'

Table 2 Correspondences between Levinson's Heuristics and Principles, and Grice's Maxims

Heuristics	*Principles*	*Grice's Maxims*	*Example*
Heuristic 1	Q-Principle	Quantity, 1	Q-Implicature: (a) Some colleagues were drunk. +> 'Not all of them were drunk.' (scalar implicature) (b) The doctor believes that the patient will not recover. +> 'The doctor may or may not know that the patient will not recover.' (clausal implicature)
Heuristic 2	I-Principle	Quantity, 2	I-Implicature: Anna turned the switch and the motor started. +> 'Anna turned the switch and then/therefore the motor started.' (conjunction buttressing)
Heuristic 3	M-Principle	Manner, 1 and 3	M-Implicature: Bill caused the car to stop. (vs. Bill stopped the car.) +> 'He did this indirectly, not in the normal way, e.g., by use of the emergency brake.' (periphrasis)

Levinson (2000: 153–164) gives some examples for Q > I, Q > M, and M > I. An example for Q > M is *It's not unlikely that Giant Stride will win the Derby, and indeed I think it is likely.* Here, as Levinson (2000: 160) points out, the first conjunct gives rise to the M-based implicature 'less than fully likely,' because of the double negative *not unlikely*, while the second conjunct triggers the Q-based implicature 'it is possible it is likely,' because of the use of *think*, which does not entail the complement clause. In this case, the Q-implicature of the second conjunct defeats the M-implicature of the first. (However, as Traugott, 2004: 11 observes, *indeed* may serve as a M-implicature cancelling device.)

The Q-principle is defined as follows (Levinson, 2000: 76):

> ***Q-principle***
> **Speaker's maxim:** Do not provide a statement that is informationally weaker than your knowledge of the world allows, unless providing an informationally stronger statement would contravene the I-principle. Specifically, select the informationally strongest paradigmatic alternate that is consistent with the facts.
> **Recipient's corollary:** Take it that the speaker made the strongest statement consistent with what he knows, and therefore that:
>
> a. if the speaker asserts $A(W)$, where A is a sentence frame and W an informationally weaker expression than S, and the contrastive expressions $<S, W>$ form a Horn scale (in the prototype case such that $A(S)$ entails $A(W)$), then one can infer that the speaker knows that the stronger statement $A(S)$ (with S substituted for W) would be false [...]
>
> b. if the speaker asserted $A(W)$ and $A(W)$ fails to entail an embedded sentence Q, which a stronger statement $A(S)$ would entail, and $\{S, W\}$ form a contrast set, then one can infer that the speaker does not know whether Q obtains or not (i.e., $\{P(Q), P \sim (Q)\}$ read as 'it is epistemically possible that Q and epistemically possible that not-Q'

The I-Principle mentioned in the Speaker's maxim requires that a speaker should not be more informative than necessary (see below). Wherever it is possible, the speaker should build on stereotypical assumptions. In the Recipient's corollary, two cases are distinguished, namely scalar implicature, involving Horn scales (named after Laurence Horn, see the next section) and clausal implicature, involving contrast sets.

In the case of *scalar implicatures*, we need a *Horn scale*: given a scale <q, p> with p as an informationally weak and q as an informationally strong element, the assertion of p implicates the negation of q. In such cases, the speaker is supposed to be as informative as possible, thus observing the Q-principle (or the maxim of Quantity). Therefore, the speaker could not say more than he actually did, and this means that the stronger statement does not hold. A classical example is the utterance p = *Some colleagues were drunk* implicating q = 'Not all of them were drunk'. In the case of *clausal implicatures*, we need *contrast sets*. Let {know, believe} be a contrast set. Then p = *The doctor believes that the patient will not recover* implicates q_1 = 'The doctor may or may not know that the patient will not recover' (Levinson, 2000: 110). The crucial point is that clausal implicatures indicate epistemic uncertainty about the truth of the embedded sentence. Note that, because <know, believe> also form a Horn scale, there is a scalar implicature as well: in this case p implicates q_2 = 'The doctor does not know that the patient will not recover.'

Well-known Horn scales include the quantifiers <all, most, many, some>, connectives <and, or>, modals <necessarily, possibly>, <must, should, may>, adverbs <always, often, sometimes>, degree adjectives <hot, warm>, and verbs <know, believe>, <love, like>. Contrast sets include verbal doublets like {know, believe}, {realize, think}, {reveal, claim}, {predict, foresee}, and others (cf. Levinson, 2000: 111).

Now consider the I-principle (Levinson, 2000: 114–115):

> ***I-Principle***
> **Speaker's maxim:** the maxim of Minimization. 'Say as little as necessary'; that is, produce the minimal linguistic information sufficient to achieve your communicational ends (bearing Q in mind).
> **Recipient's corollary:** the Enrichment Rule. Amplify the informational content of the speaker's utterance by finding the most *specific* interpretation, up to what you judge to be the speaker's m-intended [= meaning-intended] point, unless the speaker has broken the maxim of Minimization by using a marked or prolix expression.
>
> Specifically:
>
> a. Assume the richest temporal, causal and referential connections between described situations or events, consistent with what is taken for granted.
>
> b. Assume that stereotypical relations obtain between referents or events, unless this is inconsistent with (a).
>
> c. Avoid interpretations that multiply entities referred to (assume referential parsimony); specifically, prefer coreferential readings of reduced NPs (pronouns and zeros).
>
> d. Assume the existence or actuality of what a sentence is about (if that is consistent with what is taken for granted).

This principle is said to cover a whole range of implicatures: conditional perfection (9), conjunction

buttressing (10), bridging (11), inference to stereotype (12), negative strengthening (13), NEG-raising (14), preferred local coreference (15), the mirror maxim (16), specialization of spatial terms (17), and possessive interpretations (18) (cf. Levinson, 2000: 117–118).

(9) If you mow the lawn, I'll give you five dollars. +> 'If you don't mow the lawn, I will not give you five dollars.'

(10) Bettina wrote an encyclopedia and sold the rights to Elsevier. +> 'Bettina wrote an encyclopedia and then sold the rights to Elsevier.'

(11) Gustav unpacked the picnic. The beer was warm. +> 'The beer was part of the picnic.'

(12) Markus said 'Hello' to the secretary and then he smiled. +> 'Markus said "Hello" to the female secretary and then Markus smiled.'

(13) I don't like Alice. +> 'I positively dislike Alice.'

(14) I don't think he is reliable. +> 'I think he is not reliable.'

(15) John came in and he sat down. +> 'John_i came in and he_i sat down.'

(16) Harry and Sue bought a piano. +> 'They bought it together, not one each.'

(17) The nail is in the wood. +> 'The nail is buried in the wood.'

(18) Wendy's children +> 'those to whom she is parent'; Wendy's house +> 'the one she lives in'; 'Wendy's responsibility' +> the one falling on her; Wendy's theory +> 'the one she originated'

The M-principle is defined as follows (Levinson, 2000: 136–137):

M-principle
Speaker's maxim: Indicate an abnormal, nonstereotypical situation by using marked expressions that contrast with those you would use to describe the corresponding normal, stereotypical situation.
Recipient's corollary: What is said in an abnormal way indicates an abnormal situation, or marked messages indicate marked situations, specifically:
Where *S* has said p, containing a marked expression *M*, and there is an unmarked alternate expression *U*, with the same denotation *D*, which the speaker might have employed in the same sentence-frame instead, then where *U* would have I-implicated the stereotypical or more specific subset *d* of *D*, the marked expression *M* will implicate the complement of the denotation *d*, namely $\bar{d}$ of *D*.

The M-principle is supposed to cover a range of cases, among them lexical doublets (19) and rival word formations (20), nominal compounds (21), litotes (22), certain genitive (23) and zero morph constructions (24), periphrasis (25), and repetition (26) (cf. Levinson, 2000: 138–153).

(19) She was reading a tome [vs. book]. +> 'She was reading some massive, weighty volume.'

(20) Ich nehme den Flieger [vs. das Flugzeug]. (= I take the plane [vs. the airplane]) +> 'Fliegen ist nichts Besonderes für mich.' (= 'Flying is quite normal for me.')

(21) This is a box for matches (vs. matchbox). +> 'This is a (nonprototypical) box specially made for containing matches.'

(22) It took a not inconsiderable effort. +> 'It took a close-to-considerable effort.'

(23) the picture of the child (vs. the child's picture) +> 'the picture depicts the child'

(24) She went to the school/the church/the university (vs. to school, to church, to university, etc.) +> 'She went to the place but not necessarily to do the associated stereotypical activity.'

(25) Bill caused the car to stop. (vs. Bill stopped the car.) +> 'He did this indirectly, not in the normal way (e.g., by using the emergency brake).'

(26) He went to bed and slept and slept. +> 'He slept longer than usual.'

Note that only the first ('Avoid obscurity of expression') and the third ('Be brief (avoid unnecessary prolixity)') submaxims of the Gricean maxims of Manner survive in Levinson's M-principle. Levinson views the second submaxim ('Avoid ambiguity') in connection with 'generality narrowing', which is subsumed under the Q-principle (Levinson, 2000: 135). The fourth submaxim ('Be orderly') is not needed any more, because the notorious cases of 'conjunction buttressing' fall under the I-principle in Levinson's framework. Moreover, Levinson (2000: 135) notes the general cognitive status of this general semiotic principle of linearization, and he questions its status as a maxim.

It seems that many of the cases in (19)–(26) may be explained in terms of the Q- or I-principle; in other cases, it is not at all clear that we have the same denotation, as required in the Recipient's corollary of the M-principle, thus throwing into doubt whether a separate M-principle is really needed. By comparison, Horn's (1984) approach (sketched in the next section) has no separate maxim/principle of Manner. For further discussion, see Meibauer (1997) and Traugott (2004).

Obviously, the maxim of Quality and the maxim of Relevance are not maxims that figure in the

derivation of GCIs. The only comment on the maxim of Quality Levinson gives is that this maxim "plays only a background role" in the derivation of GCIs; maybe he has the sincerity conditions for assertive acts in mind (Levinson, 2000: 74). Note that Grice (1989: 34) needed the maxim of Quality to derive the implicatures in the cases of irony, metaphor, and sarcasm (*see* **Irony**). In contrast, Levinson argues that irony and sarcasm are cases of PCIs (Levinson, 2000: 386, Fn. 2), a claim that seems somewhat premature at least when considering cases of conventional irony and sarcasm. The maxim of Relevance is a maxim that, according to Levinson (2000: 74), derives only PCIs. However, this maxim seems to play a role when it comes to disambiguation and 'ellipsis unpacking' (Levinson, 2000: 174, 183) (*see* **Relevance Theory**).

In addition to the revision of the Gricean maxims just outlined, Levinson sketches a radical revision of the widely accepted Gricean view of the interaction of grammar and pragmatics according to which in language production, conversational implicatures are supposed to operate on, and follow the semantic representation of, the said (Levinson, 2000: 173). Levinson finds this view basically wrong:

> Grice's account makes implicature dependent on a prior determination of 'the said.' The said in turn depends on disambiguation, indexical resolution, reference fixing, not to mention ellipsis unpacking and generality narrowing. But each of these processes, which are prerequisites to determining the proposition expressed, may themselves depend crucially on processes that look undistinguishable from implicatures. Thus, what is said seems both to determine and to be determined by implicature. Let us call this *Grice's circle*. (Levinson, 2000: 186)

According to Levinson, there are at least five phenomena that show the influence of GCIs on sentence meaning (Levinson, 2000: 172–187). First, GCIs (of the scalar type) are involved in the disambiguation of ambiguous constructions like *some cats and dogs*, for only the bracketing *[[some cats] and dogs]*, with the appropriate implicature 'some but not all cats, and dogs in general,' is appropriate in the sentence *He's an indiscriminate dog-lover; he likes some cats and dogs*. Second, the resolution of indexicals is dependent on the calculation of GCIs, e.g., *The meeting is on Thursday.* +> 'not tomorrow' (when tomorrow is Thursday). Third, reference identification often requires GCIs, e.g., *John came in and the man sat down.* +> 'The man was not identical to John.' Fourth, in ellipsis unpacking, as in simple dialogues like *Who came? – John <came>*, the missing information is constructed on the basis of Relevance and I-Implicature. Finally, there is the case of generality narrowing, e.g., if someone utters *I've eaten breakfast* +> 'I've eaten breakfast [this morning]' where the Q-principle is activated.

In order to resolve the dilemma of Grice's circle, i.e., to account for 'pragmatic intrusion,' Levinson proposes an alternative model (Levinson, 2000: 188). This model contains three pragmatic components, namely Indexical Pragmatics, Gricean Pragmatics 1, and Gricean Pragmatics 2, and two semantic components, namely Compositional Semantics and Semantic Interpretation (model-theoretic interpretation). The output of Compositional Semantics and Indexical Pragmatics is input for Gricean Pragmatics 1. The output of Gricean Pragmatics 1 is input for Semantic Interpretation, and its output ('sentence meaning, proposition expressed') is input for Gricean Pragmatics 2, whose output is 'speaker meaning, proposition meant by the speaker.'

Whereas Indexical Pragmatics and Gricean Pragmatics 1 are presemantic pragmatic components, Gricean Pragmatics 2 is a postsemantic pragmatic component. It seems that Gricean Pragmatics 2 deals with PCIs ('indirection, irony and tropes, etc.,') whereas Gricean Pragmatics 1 deals with GCIs ('disambiguation, fixing reference, generality-narrowing, etc.'). At the heart of Levinson's approach is his analysis of GCIs, precisely because it is here that arguments for this new model of the semantics-pragmatics interaction may be found.

Division of Pragmatic Labor: Horn's Q- and R-Principles

Central to Horn's approach to implicature is the insight that implicatures have to do with "regulating the economy of linguistic information" (Horn, 2004: 13). In contrast to Levinson, Horn (1984) assumes only two principles, the Q-principle and the R-principle:

> **Q-principle**
> Make your contribution sufficient: Say as much as you can (given R).
> (Lower-bounding principle, inducing upper-bounding implicatures)
> **R-principle**
> Make your contribution necessary: Say no more than you must (given Q).
> (Upper-bounding principle, inducing lower-bounding implicatures)

The Q-principle collects the Gricean maxims of Quantity 1 as well as Manner 1 and 2, while the R-Principle collects Quantity 2, Relation, and Manner 3 and 4. The maxim of Quality is considered as unreducible, as truthfulness is a precondition for satisfying the other maxims (Horn, 2004: 7).

The Q-principle aims at the maximization of content. It is a guarantee for the hearer that the content is

Table 3 Application of the Q-Principle to scalar implicatures

Statements	*Lower bound, one-sided (what is said)*	*Upper bound, two-sided (what is implicated qua Q)*
a. Pat has three children	'... at least three ...'	'... exactly three ...'
b. You ate some of the cake	'... some if not all ...'	'... some but not all ...'
c. It's possible she'll win	'... at least possible ...'	'... possible but not certain ...'
d. He's a knave or a fool	'... and perhaps both ...'	'... but not both'
e. It's warm	'... at least warm ...'	'... but not hot'

sufficient. The hearer infers from the speaker's failure to use a more informative or briefer form that the speaker was not in a position to do so. Scalar implicatures are a case in point. The R-principle aims at the minimization of expression, and consequently, the minimization of the speaker's effort. According to Horn, this principle holds for all indirect speech acts.

The following table, which is adapted from Horn (2004: 10), shows how the Q-principle works in the case of scalar implicatures (Table 3). The two-sided reading is the default case.

According to Horn, the conflict between the Q-principle and the R-principle may be resolved, as expressed by the following principle (Horn, 1984: 22):

> **The Division of Pragmatic Labor**
> The use of a marked (relatively complex and/or prolix) expression when a corresponding unmarked (simpler, less 'effortful') alternative expression is available tends to be interpreted as conveying a marked message (one which the unmarked alternative would not or could not have conveyed).

Levinson (1987: 73) argues that Horn mixes up two things here that properly should be distinguished, namely minimization of content on the one hand, and minimization of expression on the other. According to Levinson, splitting up the maxims of Manner in the way Horn does is mistaken, because the Manner maxims are fundamentally dependent on form, and thus related to minimization of expression.

Following Horn's original work, much research has been done on Horn scales, e.g., by Hirschberg (1991), Fretheim (1992), Matsumoto (1995), Sauerland (2004), van Rooy (2004). In this connection, three further areas of research deserve to be singled out.

First, as shown in Horn (1989: Ch. 4), there is the phenomenon of *metalinguistic negation*. For example, when uttering *It's not warm, it's hot!* the first part of the utterance gives rise to the scalar implicature 'It is not hot,' but this implicature is obviously denied in the second part of the utterance. Typically, utterances of this type have a humorous, ironical, or sarcastic flair (cf. Chapman, 1996 for an overview and Carston, 1996 and Iwata, 1998 for an echo-theoretic interpretation) (*see* **Negation**).

Second, there is some discussion about the exact status of the Horn scales in the lexicon, e.g., how are elements selected for scales, how is the ordering of the elements achieved, etc. An influential approach is the one by Hirschberg (1991), who argues that there exist, in addition to lexical scales, scales that are induced pragmatically or on the basis of real-world knowledge. For example, when speaker A asks *Did you get Paul Newman's autograph?* and speaker B answers *I got Joanne Woodward's*, implicating 'not Paul Newman's,' we are dealing with a salient scale of autograph prestige <Newman, Woodward>. Consequently, Hirschberg (1991: 42) denies that there is any principled distinction between GCIs and PCIs.

Third, the economical aspect of Horn's reduction of the Gricean apparatus has recently become very attractive within *Bidirectional Optimality Theory* (cf. Blutner, 2004). This theory assumes that sentences are semantically underspecified, and therefore are in need of enrichment. A function *Gen* is assumed that determines for each common ground the set of possible enrichments. Bidirectional (i.e., taking the perspective of speaker *and* hearer) Optimality Theory then stipulates that a form-meaning pair is optimal if and only if it is taken from the set defined by *Gen*, and that there is no other pair that better fulfills the requirements of the Q- and I-principle. For an application and further discussion, see Krifka (2002) (*see* **Pragmatics: Optimality Theory**).

Relevance Theory: Carston's Underdeterminacy Thesis

Relevance theory is a cognitive theory of meaning whose major claims are that semantic meaning is the result of linguistic decoding processes, whereas pragmatic meaning is the result of inferential processes constrained by one single principle, the *Principle of Relevance*, originally proposed in Sperber and Wilson (1995) (*see* **Relevance Theory**). However, the connection to the Gricean maxim of Relevance is rather

weak, as can be seen from the following definitions (Carston, 2002; for other versions, see Wilson and Sperber, 2004):

> ***First (Cognitive) Principle of Relevance***
> Human cognition is geared towards the maximization of relevance (that is, to the achievement of as many contextual (cognitive) effects as possible for as little processing effort as possible).
> ***Second (Communicative) Principle of Relevance***
> Every act of ostensive communication (e.g., an utterance) communicates a presumption of its own optimal relevance.

Carston (2002) questions the standard division of labor between semantics and pragmatics and argues that pragmatics contributes much more to the construction of explicit meaning ('what is said') than generally assumed. Her overall aim is to establish relevance theory as a theory of cognitive pragmatics. The relevance theoretic approach is, according to Carston, "to be characterized as a sub-personal-level explanatory account of a specific performance mechanism conducted at the level of representations-and-procedures" (Carston, 2002: 11).

Carston's *underdeterminacy thesis* says that linguistic meaning generally underdetermines what is said. Pragmatic inferences are not only necessary to determine implicatures, but also to fix the proposition directly expressed by an utterance. This discrepancy between the meaning encoded in linguistic expressions and the proposition expressed by the utterance of these expressions ('what is said') is illustrated by various cases (over and above the well-known cases of ambiguities and indexical resolution): missing constituents (27), unspecified scope of elements (28), underspecifity or weakness of encoded conceptual content (29), overspecifity or narrowness of encoded conceptual content (30):

(27a) [Where is the book?] On the top shelf.
(= 'The book is on the top shelf.')
(27b) Paracetamol is better. [than what?]
(27c) This fruit is green. [which part of the fruit?]

(28a) She didn't butter the toast in the bathroom with a knife. [different stress changes the information structure]
(28b) There's nothing on TV tonight. [nothing that is interesting for you]

(29) I'm tired. [predicate is too weak]

(30) Her face is oblong. [predicate is too narrow]

In all these cases, additional inferential steps are necessary to understand what the speaker intends to say.

Since linguistically encoded meanings are necessarily incomplete, pragmatics makes an essential contribution not only to the construction of *implicit meaning* but also to the construction of *explicit meaning*. In the spirit of Relevance Theory, Carston proposes a three-level model of semantic and pragmatic interpretation of linguistic expressions.

The first step involves semantic decoding of linguistic expressions. The output of the semantic decoding is an impoverished, nonpropositional semantic representation, which Carston calls logical form. It can be described as a "structured string of concepts with certain logical and causal properties" (Carston, 2002: 57) containing slots indicating where certain contextual values must be supplied. Hence, the output of the semantic decoding device is an incomplete template or scheme, open to a range of compatible propositions.

In the second step of interpretation, the hearer reconstructs the proposition intended by the speaker through pragmatic inference. Thus, pragmatic inference bridges the gap between what is linguistically expressed (incomplete conceptual schemata/logical form) and what is said (full propositional representations). For example, when a speaker utters the subsentential expression *on the top shelf* in a given context of utterance, the hearer is supposed to reconstruct the missing constituents to yield the intended proposition 'The marmalade is on the top shelf'. The pragmatic interpretation device is constrained by the First (Cognitive) Principle of Relevance, as proposed by Sperber and Wilson (1995).

Finally, there has to be a third step of interpretation, in which the hearer determines implicatures, i.e., 'what is meant.' Thus, Carston assumes that pragmatic inference is necessary for the second and third step of interpretation. In this cognitive approach, the bulk of utterance interpretation has to be done by pragmatic inference.

The pragmatic device of interpretation relies not only on linguistic information but also on additional information gained from context, perception, and world knowledge. Here, Carston essentially refers to Searle's theory of mind, especially his notion of *Background* (cf. Searle, 1980). Utterances are interpreted against a set of more or less manifest background assumptions and practices. Consider, for instance, the following five sentences: (a) *Jane opened the window*, (b) *Jane opened her book on page 56*, (c) *Jane opened the wall*, (d) *Jane opened her mouth*, (e) *The doctor opened her mouth*. Carston assumes that the encoded meaning of the English verb *open* does not vary in all five examples, although *open* receives quite different interpretations, depending on a set of background assumptions about different practices of opening. The Background is construed as a set of

weakly manifest assumptions and practices in an individual's cognitive environment. Since the Background always supplies additional meaning to the interpretation of an utterance, the proposition expressed by an utterance cannot be fully determined by the meaning of its parts and the mode of their combination. Consequently, the principle of semantic compositionality (*see* **Frege, Gottlob (1848–1925)**) does not hold for the proposition expressed, but only for the underdetermined logical form (i.e., the first step of interpretation).

As does Levinson (2000), Carston, too, argues that Grice does not account for the fact that 'what is said' is not independent from pragmatic input. However, Carston and Levinson differ in their approaches to the question of how the pragmatic intrusion problem needs to be dealt with. As shown above, Levinson develops a pragmatic subtheory of GCIs, dealing only with the pragmatic processes involved in the elaboration of 'what is said'. By contrast, Carston favors a unitary account of all pragmatic processes, irrespective of whether they contribute to the 'what is said' or to different implicated assumptions (corresponding to Levinson's PCIs).

Carston's (2002: 377) use of the terms *explicature* and *implicature*, essentially based on Sperber and Wilson's (1995: 182) distinction between explicit and implicit assumptions/propositions, is spelled out in the following way (cf. Carston, 1988):

> **Explicature**
> An ostensively communicated assumption that is inferentially developed from one of the incomplete conceptual representations (logical forms) encoded by the utterance.
> **Implicature**
> An ostensively communicated assumption that is not an explicature; that is, a communicated assumption which is derived solely via processes of pragmatic inference.

The difference between explicatures and implicatures lies essentially in the way they are supplied: explicatures are developments of the logical form that they contain as a proper subpart, whereas implicatures are derived purely inferentially. In regard to these two kinds of pragmatic enrichment, the cognitive approach Carston promotes motivates the distinction between 'communicated assumptions' and the 'inferential steps' leading to them. Carston argues that explicatures are construed by means of interpretative hypotheses rather than by (generalized) implicatures.

Consider the example: *John came in and he sat down*. The preferred interpretation for the personal pronoun *he* in the second sentence is the coreferential one. Following Levinson, this interpretation results from an I-implicature. Carston argues that this implicature must be a proposition like '*He* refers to whomever *John* refers to', "a propositional form representing a hypothesis about reference assignment" (Carston, 2002: 151). She rejects the idea of reference assignment being an implicature and rather identifies it as an interpretative hypothesis like 'John came in and he, John, sat down,' which is derived online and only confirmed if it meets the expectation of relevance. Carston claims that this strategy is able to resolve the dilemma of Grice's circle, for the simple reason that interpretation processes can be effected simultaneously.

Finally, the cognitive approach leads Carston to reject *conventional implicatures*; these are subsumed under the procedural elements. Relevance Theory distinguishes between concepts as constituents of mental representations, and procedures that constrain pragmatic inferences. Conventional implicatures conveyed by expressions such as *moreover* and *therefore* do not contribute to the conceptual part of the utterance, but point the hearer to the kind of pragmatic processes she is supposed to perform (cf. Blakemore, 2002) (*see* **Meaning, Procedural and Conceptual**).

Bach (1994), who tries to defend the Gricean notion of 'what is said,' criticizes the notion of explicature and proposes instead the term *impliciture* (cf. also Bach, 2001). Implicitures are either *expansions* of 'what is said,' as in *You are not going to die [from this little wound]* or *completions*, as in *Steel isn't strong enough [for what?]*. In these cases, "the resulting proposition is not identical to the proposition expressed explicitly, since part of it does not correspond too any elements of the uttered sentence"; hence Bach considers it "inaccurate to call the resulting proposition the explicit content of an utterance or an explicature" (Bach, 1994: 273).

Carston views Relevance Theory as a cognitive theory of utterance understanding that aims at the subpersonal level, where processes are fast and automatic. Thus, it should be clear that this theoretical goal differs from that pursued by Grice (cf. Saul, 2002). It must be noted, however, that arguments from psycholinguistic research are called for in order to constrain the theory.

First, it may be asked how children acquire implicatures and what roles maxims, principles, and the like play in this process. There are studies on the acquisition of irony and metaphor by Winner (1988) as well as studies on the role of Gricean principles in lexical acquisition (cf. Clark E V, 1993, 2004). More recently, studies have been done on the acquisition of scalar implicatures, in particular dealing with the hypothesis that small children are "more logical" than older children and adults, in that they more

readily accept the "some, perhaps all" – reading of the quantifier *some* (cf. Noveck, 2001; Papafragou and Musolino, 2003).

Second, there is some evidence that hearers do not first compute the literal meaning, then the nonliteral or indirect meaning, but that they arrive at the nonliteral/indirect meaning earlier or in a parallel fashion (cf. Shapiro and Murphy, 1993; Récanati, 1995; Gibbs, 2002; Giora, 2003). It is obvious that experimental research is very important for implicature and explicature theory (cf. Wilson and Sperber, 2004: 623–628).

Quality Reconsidered

In the development of neo-Gricean approaches to implicature such as Horn's and Levinson's, the Gricean maxim of Quality has been neglected (*see* **Neo-Gricean Pragmatics**). Thus, genuine pragmatic matters such as metaphor, irony, sarcasm, lying, etc. have become largely unattractive for some implicature theorists, although metaphor had been featured as a cardinal case of maxim exploitation already early on (cf. Levinson, 1983: 147–162). Relevance Theory, on the other hand, which takes a stand on Grice as well as on neo-Gricean approaches, has developed an independent theory of irony; moreover, Carston (2002: Ch. 5), analyzes metaphors as instances of *ad hoc*-concept construction. In neither of these approaches, however, does the maxim of Quality play any role (*see* **Metaphor: Psychological Aspects**).

First, consider *irony*. If a speaker A utters *X is a fine friend*, referring to a person who has betrayed a secret of A's to a business rival, then the first maxim of Quality is flouted (Grice, 1989: 34). Because it is obvious that A does not believe what he says, the hearer reconstructs a related proposition, i.e., the opposite of p. The ironical implicature qualifies for the status of an implicature, because it is calculable, context-dependent, and cancellable. Note that this substitutional analysis is in contrast to the additive nature of other types of implicature. However, this approach has been criticized for several reasons: (i) The analysis cannot account for ironical questions, requests and understatements, (ii) it cannot explain the distinction between irony and metaphor, because the latter is also explained with regard to the first maxim of Quality, and (iii), it is not fine-grained enough, because it does not follow from 'He is not a fine friend' that he is not a friend at all.

The Gricean approach to irony has been most prominently attacked by relevance theorists (Sperber and Wilson, 1981; Wilson and Sperber, 1992; Sperber and Wilson, 1998). Following Sperber and Wilson, ironical utterances have four main properties: (i) They are mentioned, not used, (ii) they are **echoic** in nature, (iii) the ironical interpretation is an implicature that is derived through recognition of the echoic character of the utterance (Sperber and Wilson, 1981: 309), (iv) the ironical speaker displays a dissociative attitude towards the proposition uttered. Take the utterance *What lovely weather!* as an example. When uttered during a downpour, the speaker cannot mean the opposite, because this would be uninformative. Instead, he wants to convey that it was absurd to assume that the weather would be nice. Thus, the ironical utterance is a case of echoic mention of a previously entertained proposition. Types of echo include sarcastic repetition (31), attributed thoughts (32), norms (33) and standard expectations (34) (cf. Sperber and Wilson, 1998):

(31) A: I'll be ready at five at the latest.
B: Sure, you'll be ready at five.

(32) A: I'll be ready at five at the latest.
B: You mean at five tomorrow?

(33) A: I'll be ready at five at the latest.
B: You are so punctual.

(34) A: I'll be ready at five at the latest.
B: It's a great virtue to be on time!

Thus, the echo theory of irony does not imply that there is always an original utterance that is exactly reproduced. The echo theory is constrained in that most utterances cannot be interpreted as echoes, and echoic interpretations must contribute to the relevance of an utterance.

Several objections to this theory may be made (cf. Sperber and Wilson, 1998): (i) The notion of an echo is far too vague; it does not make sense to look for an echo in cases of conventional irony, e.g., when somebody utters *Boy, is it hot!* when it is icy cold. (ii) Because not every echoic mention is ironical, echoic mention is not sufficient to explain ironical interpretation. (iii) It is not clear why the substitution of the opposite should not be a starting point in the search for the dissociative attitude of the speaker towards the proposition. (iv) Relevance Theory cannot explain why hearers often fail to grasp the relevance of an ironical utterance.

Second, consider *metaphor*. For Carston (2002), metaphors are cases of *ad hoc* concept construction. *Ad hoc* concepts are those concepts "that are constructed pragmatically by a hearer in the process of utterance comprehension" (Carston, 2002: 322). Typical instances of *ad hoc* concepts come about via narrowing or broadening. *Narrowing* may be illustrated by utterances like *Ann is happy*, where the concept associated with *happy* in a particular context is much narrower than the encoded concept. The case

of *broadening* is exemplified by utterances like *There is a rectangle of lawn at the back*, where it is very unlikely that the encoded concept of *rectangle* is communicated. Both processes are cases of constructing an *ad hoc* concept that contributes to the explicature.

If metaphors are *ad hoc* concepts, then they are part of the explicature as well. Thus, in *Mary is a bulldozer*, the logical form of *bulldozer* is associated with an *ad hoc* concept **BULLDOZER*** differing from the concept **BULLDOZER** usually encoded by this word. In this approach, metaphor isn't an implicature any more, as Grice (1989) and Levinson (1983) would have it, but an explicature.

Recall that for Horn (1984), the maxim of Quality was unreducible. Since then, its domain of application has considerably shrunk. However, it still seems to play a role when it comes to the analysis of lying, deception, insincerity, and – maybe – irony (cf. Wilson and Sperber, 2002; Meibauer, 2005). In Levinson's (2000) approach, matters of irony, etc., are dealt with in the component called Gricean Pragmatics 2. Maybe it is there that the maxim of Quality will have a comeback. It is clear that some version of the maxim plays also a role in the definition of success conditions for assertive illocutions (*see* **Irony**).

Implicature and the Grammar/Pragmatics Interface

As has become clear from the sketch presented here of Levinson's and Carston's frameworks, pragmatic inferencing is powerful enough to influence semantic representations (*see* **Semantics–Pragmatics Boundary**). However, when it comes to pinpoint the exact relations of implicatures to illocutions on the one hand, and sentence types on the other, there still are many open questions.

First, consider implicatures *vis-à-vis* illocutions. Even if both are associated with an individual speech act, these notions refer to different entities: an additional proposition, in the case of implicature, vs. a type of act such as a promise, assertion, request etc., in the case of illocution.

An important connection between illocutions and implicatures is usually seen as obtaining in the case of *indirect speech acts* (*see* **Speech Acts; Pragmatic Acts**). According to Searle (1975), a reconstructive process that leads the hearer from the secondary illocutionary point (the 'literal' illocution) to the primary illocutionary point (the intended illocution) is similar to the scheme of reasoning that Grice proposed for conversational implicatures; step 2 of his sample derivation even includes principles of conversational cooperation (compare also the speech act schema proposed by Bach and Harnish, 1979). Accordingly, indirect speech acts have sometimes been analyzed as implicatures, for example the question *Can you close the window?*, meant as a request to close the window, a case that is related to the R-Principle as proposed by Horn (1989, 2004).

A case in point is the *rhetorical question*. Whereas Meibauer (1986) analyzes them as indirect speech acts, i.e., interrogative sentences types associated with assertive force and polar propositional content, Romero and Han (2004) analyze negative *yes/no* questions like *Doesn't John drink?* as connected with a positive epistemic implicature such as 'The speaker believes or at least expects that John drinks.' It is not clear at first sight whether such analyses are compatible; in any case, as Dascal (1994) has shown, the notions of implicature and speech act are independently motivated, and should not be confused. Thus, the question of their interrelation requires further research.

Second, consider implicatures vis-à-vis sentence types. It is widely accepted that there is a systematic connection between sentence types such as declarative, interrogative, and imperative, etc., and illocutions such as assertion, question, and request, etc.; moreover, in some approaches the existence of an intermediate category 'sentence mood' is assumed (cf. Sadock and Zwicky, 1985; Harnish, 1994; Reis, 1999; Sadock, 2004; Zanuttini and Portner, 2003). However, while it is conceivable that sentence types determine a certain illocutionary potential, the analogical notion of an 'implicature potential' has never been proposed, probably because of the authors' concentration on lexical elements that give rise to GCIs.

However, there are several observations showing that such a concept is not totally mistaken. Consider the following examples:

(35) Who is the professor of linguistics at Tübingen? +> Someone is the professor of linguistics at Tübingen.

(36) [I gave the encyclopedia to Bettina.] You gave the encyclopedia to WHOM?

(37) Visit Markus and you'll get new ideas! +> If you visit Markus then you'll get new ideas.

(38a) This is good. +> This is not excellent.
(38b) Is this good? *+> Is this not excellent?

In (35), we have the case of an existential implicature that is typically bound to *wh*-interrogatives, but shows the properties of variability and cancellability. (Its classification as an existential presupposition,

cf. Levinson, 1983: 184, has been abandoned, because it does not survive the negation test.) Example (36) illustrates the echo-*wh*-question. As Reis (1991) has persuasively argued on the basis of German data, these sentence types are neither 'echo-*wh*-interrogatives' nor *wh*-interrogatives. Instead, these utterances are regular instances of any sentence type, and their interrogative force is explained as a conversational implicature triggered by the *wh*-element (see also Reis, 1999). Another example showing that implicatures are sensitive to sentence types is the conditional imperative in (37) (cf. Davies, 1986; Clark, 1993). Finally, if elements that trigger scalar implicatures are in the scope of a question operator, the respective implicature may be blocked, as shown in (38) (the asterisk * denotes a blocked or unallowed implicature). In summary, then, there is evidence of a systematic interaction between implicatures and sentence types. The question is, then, how and where to account for this interaction.

A detailed analysis of the sentence type-implicature relation is developed in Portner and Zanuttini (2000). They concentrate on negated *wh*-interrogatives and exclamatives in Paduan, a northern Italian dialect spoken in the city of Padua:

(39a) Parcossa *no* ve-to anca ti!? (*wh*-interrogative)
Why NEG go-s.cl also you
'Why aren't you going as well!?'

(39b) Cossa *no* ghe dise-lo! (*wh*-exclamative)
what NEG him say-s.cl
'What things he's telling him!'

The point is that the NEG-element has no negative force. In principle, there are two strategies for analyzing examples like (39): First, as a special type of negation, nonpropositional, expletive, or modal in character. The second strategy, as proposed in Meibauer (1990) on the basis of German data, is to assume regular negation, and to derive the modal effect from pragmatic principles. Portner and Zanuttini (2000), drawing on the latter approach, assume that exclamatives are factive. The negation particle *no* triggers a conventional implicature, which says that the lowest element from a set of alternative elements (that are possible in a contextually given scale) is true. In cases like (39a), there is an expectedness scale {less expected < more expected}, in cases like (39b), there is an unexpectedness scale {more expected < less expected}. The scales are dependent on the respective sentence type. While it is not clear (i) whether exclamatives constitute a separate sentence type at all (cf. d'Avis, 2001), (ii) why the implicatures are of the conventional type, and (iii) how the relevant scales are obtained from the context, it should be clear that such an approach paves the way for a more empirical research on the interplay of sentences types and implicatures.

Conclusions

On the basis of the foregoing sketch of three major approaches to implicature theory, we may state some of the prevailing tendencies. To begin with, there is a striving to understand implicatures in terms of economy. This is true for Levinson's insight that implicatures help to overcome "the slowness of articulation," as becomes clear from his slogan "inference is cheap, articulation expensive" (Levinson, 2000: 29), as well as for Horn's appeal to the principle of least effort and Sperber and Wilson's view on optimal relevance. Lately, recent developments in Optimality Theory have shown attempts to integrate the interplay of maxims into their frameworks.

Second, there is a tendency to reject the classic dual distinction between 'what is said' on the one hand, and 'what is implicated' on the other. Instead, a three-level approach to meaning is favored, cf. the distinction in Levinson (2000: 21–27) between sentence meaning, utterance type meaning, and speaker meaning, or Carston's three-level model of utterance interpretation. However, there is considerable terminological confusion here, as the diagram in Levinson (2000: 195) impressively shows; confusion that has to do with the still unsolved problem of finding demarcation lines or fixing the interfaces between 'what is said' and 'what is meant.' Further discussion of the question of level architecture can be found in Récanati (2004).

Obviously, the second tendency is connected with the widely accepted view that some sort of underdeterminacy thesis is correct, and that there are presemantic pragmatic processes that are input for model-theoretic interpretation (cf. Levinson, 2000: 188), or are necessary to fix full propositional representations (cf. Carston, 2002).

As has become clear, there are still many problems to solve: the status of the maxims of Relevance and Manner, the distinction between GCI and PCI, the status of conventional implicatures, the interaction of implicatures with illocutions and sentence types, to name only a few. Besides, the role that implicatures play in many areas, such as those of language acquisition and language change, awaits much further research.

IN/ING Variable

K Hazen, West Virginia University, Morgantown, WV, USA

© 2006 Elsevier Ltd. All rights reserved.

The sociolinguistic variable (ING) accounts for the variation of the production of two phonetic forms: a coronal nasal [n] and a velar nasal [ŋ], as in *I was walki*[n] and *Walki*[ŋ] *is fun*.

This variable has been a staple of sociolinguists since the advent of the modern field. Scholars of language variation have studied this variable since the 1950s, and historical linguists have argued its origins since the end of the 19th century (although most of the attention by historical linguists came as a result of their study of the development of gerunds and the progressive): Callaway (1889, 1929), Curme (1912), Poutsma (1923), Langenhove (1925), Gaaf

IN/ING Variable

K Hazen, West Virginia University, Morgantown, WV, USA

© 2006 Elsevier Ltd. All rights reserved.

The sociolinguistic variable (ING) accounts for the variation of the production of two phonetic forms: a coronal nasal [n] and a velar nasal [ŋ], as in *I was walki*[n] and *Walki*[ŋ] *is fun*.

This variable has been a staple of sociolinguists since the advent of the modern field. Scholars of language variation have studied this variable since the 1950s, and historical linguists have argued its origins since the end of the 19th century (although most of the attention by historical linguists came as a result of their study of the development of gerunds and the progressive): Callaway (1889, 1929), Curme (1912), Poutsma (1923), Langenhove (1925), Gaaf

(1928), Jespersen (1926), Rooth (1941), Dal (1952), Mossé (1938), Irwin (1967).

Several properties of the (ING) variable have maintained its scholarly popularity. First, a wide variety of people talk about it: For over two centuries, nonlinguists and linguists alike have discussed for various dialects the prescriptive values of 'G-dropping,' the nonacademic name for the [ɪn] variant of this variable. As reported in Houston (1985: 338), Lowe provides the following homophonous pairs of words: *coffin* and *coughing*, *coming* and *cumin*, *heron* and *herring*. Each of these pairs indicates that the author was aware that <ing> was linked to an [ɪn] articulation. The first negative prescriptive evaluation Houston found derives from a letter to the editor of a British newspaper in 1902 which decried "a disloyal crusade against the Queen's English . . . which . . . will . . . deprive present participles of their final 'g.' (1985: 338)" By the 20th century, it appears that the public assumed the velar nasal articulation to be the basic form from which the coronal pronunciation derived.

The second property of the (ING) variable which makes it popular among sociolinguists is the relatively easy set of methodologies involved in its collection. For sociolinguists in research projects or for pedagogical class projects, reliably conducting analysis of (ING) is relatively easy: trained undergraduates and seasoned professors can both yield dependable results for recorded interviews as the two variants are impressionistically simple to discern.

Third, and perhaps most important, the sociolinguistic variable (ING) has a richly complex path of diachronic variation while maintaining a relatively clear synchronic profile. Synchronically, (ING) variation can be used to map out social dimensions; diachronically, (ING) variation involves several realms of language change for over a millennium. For sociolinguistics, the (ING) variable is like the fruit fly (drosophila) for biology, a complex subject yielding results for researchers with different goals. (ING) has had diachronic (phylogenic) development; its synchronic (ontogenetic) variations in the speech community reflect mutations in areas of the lexicon, morphology, and phonology as well as extensive social variation.

Historical Roots of ING

The (ING) variable has had a long diachronic path. Like several of its Germanic sisters, Old English had the roots of *-ing*. Along the path towards Modern English, these separate, apparently stable forms merged to become the modern suffix *-ing*. Irwin (1967) reported that the feminine suffix *-ung* for verbal nouns was replaced by the masculine suffix for verbal nouns, *-ing*: e.g., OE *hael* 'to heal'; *haelung* 'the act of healing' was rendered as *haeling*. By the end of the 13th century, this gender distinction appears to have been completely lost, with the *-ing* form as the sole survivor.

Irwin (1967) examined <nd> and <ng> forms from the 8th to the 15th centuries; her scholarship indicates that the majority <nd> forms were replaced by the <ng> forms in the 15th century. It appears that <nd> forms did not replace <ng> forms: the alternations were not random confusion but a unidirectional replacement. Houston (1985: c. 100) reported that the geographic area where *-ing* replaced *-ind* in the 15th century maintained higher probabilities of the velar variant in the 20th century. It is partially with this alternation between *-ing* and *-ind* that the alternation between the velar and alveolar nasals of modern *-ing* arose. The full diachronic story appears to have other possible influences (Houston, 1985: 164), but these three suffixes were the major players.

In the transition from Middle to Early Modern English, Houston (1985) described a vowel situation which may have led the orthographic overlap of <ing> for both *-inde* and *-inge*. Several studies reported variability of the preceding vowel between [ɪ], [ə], and even high tense [i] (Houston, 1985; Woods, 1978). In the south of England, where the printing houses of London were establishing the orthographic standards, the high vowel before the nasal allowed the coronal nasal of *-ind* to be heard more as a velar. This influence may have contributed to the merger of the suffixes. Houston, in contrast with previous scholars, argued for the establishment of the modern spelling system as a reflection of the lack of distinction between verbal and nominal forms of the suffix. Previous scholars, for example Wyld (1936), had argued that a pre-Early Modern English [ɪn] articulation was affected by the orthographic <ing>, resulting in a pronunciation of [ɪŋ].

Prescriptive Commentary

Of note for (ING) is the use of the orthographic apostrophe, as in *walkin'*. Although this is the clear favorite for orthographically marking the coronal [n], it is relatively new in relation to the actual alternation between these forms. The apostrophe does not appear until the 19th century (Houston, 1985: 53). Before this convention, Houston argued that a final <e> marked the released velar stop in forms such as *sinnynge*. For those authors of fictional works who used the apostrophe to mark a speaker as of lower socio-economic status or less educated, Houston (1985: 350) did not find that the apostrophe's marking of [n] follows the grammatical constraint found

for modern speakers or pre-apostrophe documents. She claimed (1985: 362) that the authors did not share these grammatical constraints and were not aware of them. The presence or absence of <e> does correlate with the grammatical constraint (Houston, 1985: 361).

Conditions of Synchronic Variation

The sociolinguistic variable (ING) encompasses, in part, the English inflectional progressive morpheme and the English derivational gerundial morpheme, both spelled <ing>, as in the following examples: *she is walking*; *walking is fun*. Labov (1989: 87) reported a grammatical set of conditionings within an implicational hierarchy where the [ɪn] variant was favored "most in progressives and participles, less in adjectives, even less in gerunds and least of all in nouns like *ceiling* and *morning*." With these monomorphemic lexemes such as *ceiling*, the variation between the coronal and velar nasals is not an alternation of morphemes, but a switching of places of articulation. As a sociolinguistic variable, (ING) is a coherent whole with two variants; however, (ING) is not the result of a single linguistic process.

Most studies focus on unstressed *-ing*, following Labov (1972). Thus, monosyllabic words such as *ring*, *king*, *sing*, and *bring* are not considered possible environments. For most speakers surveyed, this category of lexemes does not vary in the velar place of articulation of its final nasal. Stress patterns may also affect realizations of *-ing* in multisyllabic words. Houston (1985: 22) found the velar variant to be nearly categorical in the words *everything* and *anything* but nearly absent in the words *something* and *nothing* for Southern U.S. speakers, although this pattern was not robust for her British urban data. Houston reasons that the *-ing* syllable receives secondary stress in *everything* and *anything* but not in the disyllabic words *something* and *nothing*.

Beyond prosodic concerns, another phonological factor Houston (1985: 19) discussed is the regressive homorganic assimilation and the progressive homorganic dissimilation for [n] and [ŋ]. For example, in *peeling carrots* the following velar favors an [ŋ] and *feeling tired* the following alveolar favors [n]; in *speaking up* and *sending out*, the preceding consonants disfavor homorganic articulation of [ŋ] and [n] respectively. However, Labov (2001: 87) claimed that "there seems to be no strong phonological conditioning before following velars or apicals."

One important typological quality of these phonetic variants relates to implicational tendencies: the velar nasal is not as common as the alveolar nasal in the world's languages; its distribution in the inventory of English sounds is more restricted; children acquire the velar nasal latter than the alveolar (Grunel, 1987). It could well be that such tendencies for [ŋ] to be disfavored could have played a role throughout the history of these forms.

An important quality of the (ING) variable is that no modern study has shown a change in progress. Despite its abundant linguistic and social variation, it does not appear to be undergoing diachronic variation currently.

Social Factors

Fischer (1958) employed (ING) in his foundational work on a New England village. Labov (1966) was the first study to detail social constraints on (ING). This work demonstrated both socio-economic effects, specifically an inverse relationship between socioeconomic status and rate of [ɪn], and stylistic effects, specifically an inverse relationship between formality and the rate of [ɪn]. In general, these results have been found in every community where (ING) has been studied: the variant [ɪn] is associated with both informality and lower socioeconomic status (see Labov, 2001: ch. 3).

Many sociolinguistic studies have examined the (ING) variable, including the following: Shuy *et al.* (1968) for Detroit, Labov (2001) for Philadelphia, Trudgill (1974) for Norwich, Woods (1978) for Ottawa, Reid (1978) for Edinburgh, Douglas-Cowie (1978) for Northern Ireland, and Wolfram and Christian (1976) for West Virginia. Variation in the (ING) variable has been noted in Australia, Canada, England, Ireland, New Zealand, Scotland, and the United States. Only in South Africa is there a native English-speaking population which reportedly does not vary between [n] and [ŋ] for the (ING) variable (Gordon and Sudbury, 2002: 81). Labov (2001: 90) reported that "Southern States English, northern English, and Scots stand out [because] there the /in/ form is used almost exclusively in speech, even of the most formal kind."

Within the United States, researchers have studied (ING) usage in both African-American and European-American communities. Anshen (1969) compared these two ethnic groups in the southern United States, finding several similarities: For both ethnic groups, men use [ɪn] more than women.

(ING) is one of the consummate sociolinguistic variables. Its complete story involves both diachronic and synchronic variation, both internal and external factors. Three original Old English forms merged over the centuries into one form for one regional dialect. This one dialect established the prescriptive orthographic standard as <ing>, covering for two

different suffixes and monomorphemic forms. The modern grammatical patterns for (ING) are now a synchronic echo of these previously heterophonous morphemes. Social differentiation arose between the two forms, where the southern English [ŋ] was considered standard and the [n] nonstandard. This social distinction may have arose after the regional differentiation came to the level of consciousness.

Incorporation

J M Sadock, University of Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Incorporation is the grammatical phenomenon whereby a word contains morphemes that can be understood as separate elements of a proposition. The term is sometimes used more narrowly to refer only to cases where the morphemes are joined by compounding or where the grammatical or semantic relation is restricted in one way or another, and it is sometimes used more generally to include certain cases where the morphemes are not clearly joined morphologically at all.

The most discussed examples of incorporation come under the rubric of noun incorporation (NI), particularly those in which a noun and a verb are compounded, producing a structure in which the noun expresses an argument or part of an argument of the verb. In the most typical kind of NI, the noun that is compounded with the verb designates the objective or theme argument of the predicate and it was in this sense that the word *Einverleibung* was originally used in describing facts of "Mexican" (Náhuatl) by von Humboldt (1988), who contrasted a sentence with an independent verb and object: *ni-c-qua in nacatl* "I-it-eat the meat" with the incorporated form *ni-naca-qua* 'I-meat-eat'.

Other grammatical and semantic relations that come under the heading of NI include instruments, locatives and goals, equatives, possessa, and, to a limited extent, subjects, as illustrated by these examples from Sapir (1911):

da^{a}-sgek!eīha (Takelma)
ear-keep.listening
'He kept listening'

ni-k-tle-watsa in nakatl (Náhuatl)
I-it-fire-roast the meat
'I roast it in a fire'

djī-yā-dja-s (Yana)
taste-person-off,away-PRES.FEM
'It tastes like human flesh'

buī-djalil$^{\varepsilon}$ ai'gadú-isi-wandja (Yana)
kick-calf.of.leg-PRES-3singSUBJ.1singOBJ
'He kicks my calf'

ti-karíh-ihu$^{\varepsilon}$ (Pawnee)
3sg.INDIC-stone-be.large
'The stone is large'

Roughly speaking, the more like a subject a noun is, the harder it is to incorporate; the more animate a noun is, the harder it is to incorporate; and the more definite it is, the harder it is to find in a NI structure. Potential examples such as *John-eat the meat* with *John* as an incorporated noun have not been attested.

NI has also been taken to include examples where derivational morphology rather than compounding is the morphological technique used in forming the complex verb, as in the following example (Sadock, 1980), where-*lior*-is a bound morpheme that never occurs as an independent verb:

Suulut timmisartu-lior-poq. (West Greenlandic Inuktitut (Greenlandic Inuktitut))
Suulut airplane-make-INDIC.3sg
'Sulut made an airplane'

Examples in which verbal meanings combine are sometimes referred to as verb incorporation, and similarly for preposition incorporation, adverb incorporation, and adjective incorporation, where adjective meanings combine with nouns as in Chukchee (Chukot).

The demotion of independent nominals to a kind of verbal adjunct, often lacking case markers, determiners, and the like, has also been dealt with as NI even though the facts of such languages as Greek, Hungarian, and Niue, etc., do not support the conclusion that the noun forms a morphological unit of any kind with the verb. Still, there are many analogies.

Controversy over the nature of NI arose already in the early 20th century in an exchange between Alfred Kroeber and Edward Sapir. Kroeber (1909) had defined noun incorporation, following von Humboldt's example, as "...the combination into one word of the noun object and the verb functioning as a predicate of a sentence." Sapir (1911) objected, saying that "...the combining of a morphologic requirement with an independent syntactic one yields, on general principles, a definition of too narrow a scope for the discussion of as fundamental a problem as noun incorporation...." Sapir instead offered an entirely morphological definition: "It is this process of compounding [a noun and a verb to form a verb] that it is here proposed to call noun incorporation, no matter what the syntactic function of the noun logically is."

Much the same controversy that Kroeber and Sapir were involved in reemerged 70 years later in the debate between adherents of some fairly strong version of the lexicalist hypothesis, including both formalists and functionalists, and those who did not accept it. The question is whether there is any independent syntactic or semantic status to the parts of a word that might be construed as a verb and an object or whether the word is to be taken as syntactically and/or semantically indivisible, regardless of its internal morphological structure.

Representing the anti-lexicalist point of view, Sadock (1980) argued that certain facts of West Greenlandic Inuktitut indicated that the word is not a syntactic atom (and hence not a semantic atom either), presenting evidence that the incorporated noun functions as the syntactic head of an NP object. Eskimo (Eskimo-Aleut) languages, however, use suffixal, denominal verbalizing affixes rather than compounding as the morphological technique for joining the elements of the word and had therefore been specifically excluded by Sapir as offering genuine examples of NI. The evidence for the syntactic function of

the incorporated noun in West Greenlandic cited by Sadock (1980) included the fact that:

1. Any noun in the language may be incorporated.
2. The incorporated noun may be modified by an external phrase.
3. The incorporated noun may be specified by an external possessor.
4. The external modifier agrees with the incorporated noun.
5. The incorporated noun may be referential and may introduce new entities into the discourse.
6. The incorporated noun cannot be "doubled" by a full external NP.

Partly similar facts have been adduced in Southern Tiwa, Mohawk, and many other languages where the morphological facts do fit Sapir's definition.

Mithun (1984), Di Sciullo and Williams (1987), Rosen (1989), van Geenhoven (1996), and others, however, continued to maintain a lexicalist point of view from a variety of different theoretical perspectives. Mithun proposed an evolutionary scheme for the development of NI that included the following four-way typology of noun–verb compounding. This typology was presented as a hierarchy such that no higher type should exist in a language without all of the lower types being present as well:

Type I: Lexical compounding NI, in which the compound expresses a "unitary concept" and the noun is not referential and hence cannot be modified or determined. When applied to a transitive verb, it reduces the valence, producing an intransitive.

Type II: Case-manipulating NI, which resembles Type I, but keeps the valence intact so that another argument may assume the grammatical status of the incorporated noun.

Type III: Discourse structure manipulating NI, which "... is used to background known or incidental information." The incorporated noun may refer to a previously introduced topic but does not present information, that "... might obstruct the flow of information."

Type IV: Classificatory NI, in which a general N is incorporated producing a V of narrowed meaning. The valence of the verb is not altered, so it may be accompanied by a more specific external NP that identifies the argument rather than simply indicating the kind of thing it is. The external argument may "double" the incorporated noun if it is modified and therefore narrower in meaning.

Mithun's discussion is important because it stresses that not all NI is necessarily similar within a single language let alone across languages. It also provides a useful catalogue of some of the ways that incorporative phenomena vary in their functional, semantic, and syntactic properties. The four-way classification, however, is not exhaustive, there being numerous examples of NI in the literature with mixed properties from more than one of the classes. There are also facts, such as the possibility of introducing a discourse topic in incorporated form, that do not appear to be allowed according to Mithun's taxonomy.

In the cases of NI taken up by Mithun, "... all languages which exhibit such morphological structures also have syntactic paraphrases." It is natural for the incorporated form and the independent form to differ semantically or functionally, but incorporation is obligatory in some languages in some circumstances and where it is, there is no contrast with an independent form and therefore no necessary functional role for NI. Harrington (1910) had already observed for the Tiwa of Taos Pueblo, where, he wrote, "The singular direct object *must be compounded*" [emphasis original]. In the related language of Isleta Pueblo (Southern Tiwa), Allen *et al.* (1984) say that inanimate direct object heads of NPs must be incorporated whether or not they occur with a numeral or demonstrative. The numeral or demonstrative remains as an independent expression outside the verb in such a case. It is difficult to see what the functional role of incorporation might be in the absence of a contrast with a competing form of expression.

yede ti-shut-pe-ban (Southern Tiwa)
that 1sing.A-shirt-make-PAST
'I made that shirt.'

(The personal prefix here indicates the subject's person and number and the class of the object, in this example class A, in agreement with *shut* 'shirt'.)

In the formal camp, the important work of Baker (1988) reoriented the analysis of NI within GB. He essentially abandoned the lexicalist hypothesis, arguing that a good deal of the known behavior of NI constructions could be predicted by assuming that incorporation is the movement of a syntactic head under the restrictions that movement is otherwise known to obey. He showed, for example, that the well-documented resistance of subjects to incorporate, particularly transitive subjects and agentive intransitive subjects, could be reduced to the fact that the trace of movement of such an incorprated noun would not be properly governed. There are, however, exceptions to the ban on incorporation of transitive subjects, notably in Koyukon Athapaskan (Koyukon) (Axelrod, 1990), and though the examples in Koyukon are "potent" inanimates and might be

analyzed in such a way as to allow proper government under incorporation, the treatment would have to be *ad hoc* for Koyukon and not applicable to most other languages with NI where incorporation of a transitive subject is quite impossible.

kko' sots'eeyhyeedzoyh (Koyukon Athapaskan)
kko'-sots'eeyh-ye-ee-Ø-dzoyh
around-wind-OBJ.3sing-MOD/ASP-CLASS-MULTIPLE.OBJ
'The wind is moving them around.'

Baker uses the same head-movement mechanism for deriving productive morphological causatives as verb incorporation and applicatives as preposition incorporation. Morphological causatives had been the subject of debate concerning the lexicalist hypothesis in the 1960s and 1970s. In mainstream syntactic research, the lexicalist approach held sway until Baker's work made a syntactic analysis of causatives respectable once again. More controversially, Baker's work also treated antipassives as the incorporation of an indefinite object and passives as a species of verb incorporation.

Sadock (1985) used the facts of syntactically important NI to argue for a model in which morphology and syntax are autonomous components, each generated separately and possibly producing noncongruent structures for the same example. NI would be an example of such noncongruence rather than movement within the syntactic module. A lexicalist account of NI in the HPSG framework is found in Malouf (1999).

Di Sciullo and Williams (1987), however, argued that a lexicalist account could be maintained in the face of Baker's arguments. Rosen (1989) also took a strictly lexicalist position on the treatment of NI, reducing Mithun's typology to just two members: Compound NI and Classifier NI. If Mithun's scheme was not exhaustive, then Rosen's is *a fortiori* not. More recently, van Geenhoven (1996) provided a syntactically lexicalist account of West Greenlandic NI by using sophisticated semantic techniques.

It seems fair to say, though, that incorporative phenomena in natural languages have now resulted in the widespread (but certainly not universal) rejection of the lexicalist hypothesis in favor of derivation of at least some noninflectional word structure within the syntax in a manner rather similar to that of generative semantics.

Indefinite Pronouns

Ö Dahl, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

General

In traditional grammar, the term 'indefinite pronouns' is often used quite widely, comprising not only words like *something* and *anybody*, but also generic pronouns such as English *one* or French *on*, quantifiers such as *few*, *many*, *all*, and *every*, and 'identity pronouns' such as *other* and *same*. Given the heterogeneity of the category thus understood, a more restrictive approach seems motivated, in which the term is used only of expressions with indefinite reference in a narrower sense (Haspelmath, 1997). This would, for English, basically leave us with *some* and *any* and their derivatives, also including words such as *somewhere* and *anytime* which are, strictly speaking, pronominal adverbs, but which semantically share most of their properties with the other members of the respective series and therefore deserve to be treated together with them. ('Indefinite proforms' would probably be the most 'correct' term.) A further delimitation has to be made in that more highly grammaticalized morphemes such as indefinite articles should be not be included, in keeping with the tradition not to see them as proforms. It should be noted, however, that semantically, indefinite pronouns have much in common with other indefinite noun phrases.

As we have already seen, English indefinite pronouns form what we can call 'series' – sets of pronouns sharing an 'indefiniteness marker' such as *some* and *any*. Each member in the series is connected to an ontological category such as time, place, person, thing, quantity, etc. (it may be noted that these categories are essentially those postulated by Aristotle – in fact, in choosing his categories, Aristotle at least partly seems to have been guided by the Greek pronoun system). Not infrequently, the morpheme that identifies the ontological category is formally identical to the corresponding interrogative pronoun, as in German *irgendwo* 'somewhere,' with indefiniteness marker *irgend-* and ontological category marker *wo* 'where,' or Russian *kto-to* 'someone,' formed by adding the indefiniteness marker *-to* to the interrogative pronoun *kto* 'who.' As noted by Haspelmath (1997: 24), indefinite pronouns universally tend to be derived, and typically from interrogative pronouns – the opposite direction is hardly attested.

The *Some–Any* Distinction

The existence in English of two series of indefinite pronouns – the *some* series and the *any* series – has given rise to an extensive discussion in contemporary linguistic and philosophical literature. In the development of generative-transformational grammar, the distribution of *some* and *any* in English was first seen as a purely syntactic problem that could be given a relatively straightforward syntactic solution (Klima, 1964) but after some time it became clear that the factors that governed the choice were at least partly pragmatic (Lakoff, 1969). Already in the pre-Chomskyan period, linguistically oriented logicians such as Hans Reichenbach tried hard to make sense of the relations between *some* and *any* and the quantifiers of predicate logic (Reichenbach, 1980). In the ensuing discussion, which is still going on, new frameworks such as Jaakko Hintikka's game-theoretical semantics have been invoked as helpers. In a crosslinguistic perspective, it may be noted that the existence of more than one series of indefinite pronouns is a rule rather than an exception, but precise analogues to *some* and *any* are hard to find in other languages. Yet the distribution of the English indefinite pronouns obeys general principles which manifest themselves in seemingly chaotic but nonetheless systematic patterns in human languages.

In English, the *any* series can be said to have two major types of use. The first one is in contexts connected with 'negative polarity' in the wide sense, also including, for example, questions and conditional protases. We thus get a contrast between the negated sentence (2), with *any*, which contrasts with the affirmative sentence, (1), where *some* is used.

(1) I saw someone

(2) I did not see anyone

The second type of use where we find the *any* series is for expressing what is often called 'free choice,' as in

(3) Anybody can do this

Attempts to reduce the ambiguity between the negative polarity use and the free choice use (e.g., Reichenbach, 1980: 105) to a difference in scope run into problems with examples where stress is used to disambiguate the two readings (Dahl, 1970: 39), as in *Can I take any* ***apple?*** and *Can I take* ***any*** *apple?*

The prominence of negative polarity in the choice between different series of indefinite pronouns, and the particular combination of negative

polarity readings with 'free choice,' is far from universal. Other distinctions, notably ones having to do with the specificity of referents, are often more salient. For instance, in Russian, the two series in *-to* and *-nibud'* may disambiguate classical cases such as the following, where only *some* is possible in English:

(4) ona xočet najti kogo-to
she *want*.PRES.3SG *find*.INF *someone*
ambiguous but with the preferred reading 'she wants to find someone [a specific person]'

(5) ona xočet najti kogo-nibud'
she *want*.PRS.3SG *find*.INF *someone*
only nonspecific: 'She wants to find someone [nobody in particular]'

Functions of Indefinite Pronouns

Taking a crosslinguistic perspective, Martin Haspelmath defined nine different functions of indefinite pronouns (Haspelmath, 1997):

1. specific, known to the speaker (***Somebody*** *called while you were away, guess who!*)
2. specific, unknown to the speaker (*I heard* ***something****, but I couldn't tell what kind of sound it was*)
3. nonspecific, irrealis (*Please try* ***somewhere*** *else*)
4. polar question (*Did* ***anybody*** *tell you anything about it?*)
5. conditional protasis (*If you see* ***anything****, tell me immediately*)
6. indirect negation (*I don't think that* ***anybody*** *knows the answer*)
7. standard of comparison (*In Freiburg the weather is nicer than* ***anywhere*** *in Germany*)
8. direct negation *(I didn't see* ***anybody****)*
9. free choice (***Anybody*** *can solve this simple problem*).

Haspelmath claims that these functions can be ordered in an 'implicational map,' as in Figure 1, where an indefinite pronoun series will always express a contiguous subset of functions, as shown in Figure 2, representing English, Russian, and Japanese. (For clarity, only two series of pronouns from each language are shown.) In addition, however, the choice between indefinite pronouns can be influenced by factors not represented in Figure 1, such as the speaker's expectations – for instance, if s/he expects a positive or a negative answer to a question, and differences in focus or emphasis, including distinctions relating to the notion of scalarity.

Figure 1 Haspelmath's implicational map for indefinite pronouns. Adapted from Haspelmath M (1997). *Indefinite pronouns.* Oxford: Clarendon Press, with permission.

Diachronic Developments

Diachronically, indefinite pronouns tend to arise from a limited number of sources, the most common being phrases with original meanings such as 'whatever it may be,' 'it does not matter which,' or 'it is the same which,' which come to acquire the 'free choice' function and then spread first to the functions adjacent to it in Figure 1 and then to more distant ones. For instance, the Russian indefinite pronouns ending in *-nibud,'* such as *chto-nibud'* 'something, anything,' which derives from *chto ni budi* 'whatever may be,' thus a typical expression of free choice. In modern Russian, however, *chto-nibud'* has a number of uses (see Figure 2) in which the free-choice meaning is weakened or inappropriate. An other possibility is for indefinite pronouns to arise at the other end of the implicational map – from 'dunno' constructions like the one exemplified by Old Norse *ne wait ek hwariR* 'I do not know who,' which is the source of

Figure 2 Functions of indefinite pronouns in English, Russian, and Japanese. Adapted from Haspelmath M (1997). *Indefinite pronouns.* Oxford: Clarendon Press, with permission.

Scandinavian indefinite pronouns such Swedish *någon* 'some, someone', which has expanded its domain of use so as to be possible in all the functions in Figure 1 (this is crosslinguistically somewhat exceptional). (In the Latin phrase *nescio quid* 'something' the origin is still transparent.) The two diachronic paths are similar in that somewhat similar literal meanings – 'it does not matter which' or 'I do not know which' – are backgrounded or disappear, but they differ in whether they start at the most or least specific end of the implicational map. A third diachronic source of indefinite pronouns is combinations of focus particles (*even*, *also*) with interrogative pronouns, nouns with general meaning, or the numeral 'one,' as in Japanese *nan-demo* 'whatsoever,' from *nani* 'what' and *-demo* 'even.' Sometimes interrogative pronouns used by themselves obtain functions as indefinite pronouns. This appears to happen particularly often in contexts such as conditional protases, as in Latin *Si* ***quis*** *vult post me sequi*... "if someone wants to follow me...". Nouns with general meanings such as 'person' and 'thing' can also develop uses in which they become indistinguishable from indefinite pronouns.

Inherently Negative Pronouns

In negative contexts, indefinite pronouns such as the members of the *any* series compete with 'inherently negative pronouns' such as *nobody*. Cf. English:

(6) I did not see anybody

(7) I saw nobody

However, as noted by Haspelmath (1997: ch. 8), the distinction between indefinite and inherently negative pronouns is far from unproblematic: originally indefinite pronouns sometimes obtain a negative import when used by themselves, for instance in the answers to wh-questions. Thus, in French, 'never' is expressed by a combination of the negation word *ne* and the pronominal adverb *jamais*, with the earlier meaning 'ever' (originally deriving from Latin *jam magis* 'even more'). However, used by itself in the answer to a question, *jamais* now means 'never,' without any support by a negative word. Compare also an expression such as *jamais vu* 'never seen.' In a question like (8), on the other hand, *jamais* can still be used without negative import:

(8) Es -tu jamais allé en France?
are you ever go.PP to France
'Did you ever go to France?'

Such facts may be taken as support for treating inherently negative pronouns as a subspecies of indefinite pronoun, as Haspelmath (1997) suggests. On the other hand, in some languages, inherently negative pronouns behave in a way that suggests that they are even synchronically derivable from a combination of a negation morpheme and an indefinite pronoun. Thus, in Swedish, a negative pronoun such as *ingenting* 'nothing' can only be used if the result of replacing it by a negation *inte* 'not' immediately followed by an indefinite such as *någonting* 'something,' is also grammatical. We thus obtain contrasts as illustrated by the following examples.

(9a) Jag köpte inte någonting
I buy.PAST not nothing
'I did not buy anything' (negation adjacent to indefinite pronoun)

(9b) Jag köpte ingenting
I buy.PAST nothing
'I bought nothing' (negation adjacent to indefinite pronoun)

(9c) Jag har inte köpt någonting
I have not buy.SUP nothing
'I did not buy anything' (negation non-adjacent to indefinite pronoun)

(9d) *Jag har köpt ingenting
I have buy.SUP nothing
'I have bought nothing'

Indeterminacy, Semantic

M Hymers, Dalhousie University, Halifax, Nova Scotia, Canada

© 2006 Elsevier Ltd. All rights reserved.

Contemporary philosophy has presented two significant challenges to the determinacy of meaning, one contentiously associated with Ludwig Wittgenstein through the work of Saul Kripke (*see* **Rules and Rule Following**) and the other, the topic of this entry, traceable to the behaviorism of W. V. Quine by way of his thought experiment concerning radical translation.

Quine purports to offer two distinct arguments for semantic indeterminacy, which he sees as a consequence of the thesis of the *indeterminacy of translation*: "manuals for translating one language into another can be set up in divergent ways, all compatible with the totality of speech dispositions, yet incompatible with one another" (1960: 27). This thesis has semantic implications for Quine, because as a behaviorist he holds that meaning is nothing above and beyond what is preserved in translation. This article will discuss both arguments for this thesis and reactions to them in separate sections below, focusing largely on the so-called argument 'from below' (1970: 183).

The Argument from Below

The radical translator, says Quine, is someone who has at her disposal only the behavior of the speaker of the alien tongue she is trying to translate and the observable objects and events that grace the locale she shares with the speaker. More carefully, Quine focuses not on those objects and events themselves, but on the stimulations they produce at the speaker's nerve endings (*see* **Radical Interpretation, Translation and Interpretationalism**) and on the speaker's observed disposition to assent to or dissent from sentences that the translator puts to her as queries under given *stimulus-conditions*. If she can formulate correct hypotheses about the speaker's terms for affirmation and dissent, then this evidential constraint entails that the field linguist can translate *observation-sentences*, which are among the class of sentences to which assent is cued directly to particular occasions and to which, moreover, assent varies little or not at all with changes in the background information available to the speaker (1960: 42). The thought here is that reports of observations are reports of things observed on particular occasions (unlike talk of biological speciation or social justice), and those things are importantly independent of the speaker's background beliefs and mental states (unlike hallucinations, for example). Each such sentence has what Quine calls a *stimulus-meaning* – the ordered pair of its positive stimulus-conditions (those prompting assent to the sentence) and its negative stimulus-conditions (those prompting dissent from the sentence). Logical connectives such as 'not,' 'and,' 'or,' and 'all' can also be translated, because "one's interlocutor's silliness, beyond a certain point, is less likely than bad translation" (59). This 'principle of charity' (59n) has it that, for example, a speaker will not typically affirm both a sentence and its negation. We can, as well, identify but not necessarily translate sentences that are *stimulus synonymous* (those provoking assent and dissent respectively under exactly the same stimulus conditions) and sentences that are *stimulus analytic* – those to which the speaker will assent, if not to nothing, on every stimulus occasion (54–55).

Quine begins with sentences because a speaker assents to (or dissents from) utterances of sentences, not to (or from) isolated subsentential terms. But a thorough 'translation manual' should tell us how to match up individual words or other subsentential expressions (1960: 69). The radical translator may thus formulate a set of *analytical hypotheses* (68), which break down sentences into their component parts, words, which can then be found in other sentences. A survey of their occurrences in different sentences makes it possible to pair those words with words of the translator's language, eventually yielding a comprehensive translation manual, whose adequacy can be further tested by recombining the isolated words into new sentences and observing the speaker's pattern of assent and dissent to them. However, Quine contends, there will always be more than one overall system of analytical hypotheses that will yield workable translations, because local incompatibilities in competing hypotheses can always be compensated for by making changes elsewhere in the system. Thus, to take a trivial case, in the French '*ne . . . rien*,' '*rien*' can be translated either as 'anything' or as 'nothing,' says Quine, "by compensatorily taking '*ne*' as negative or as vacuous" (1969a: 37).

Worse still, even if one's analytical hypotheses isolate a particular word, the reference of that word may itself remain 'behaviorally inscrutable' (1969a: 35), for there is no empirical test that will decide between translations of the word '*gavagai*' as 'rabbit' and as 'undetached rabbit parts,' given that apparent evidence against one translation can again be compensated for by making adjustments elsewhere in

the system (*see* **Holism, Semantic and Epistemic**). Inquiries whether this *gavagai* (rabbit) is the same as that *gavagai* (rabbit) may as easily be taken as inquiries whether this *gavagai* (rabbit part) belongs with that *gavagai* (rabbit part) (33). Beyond the level of observation-sentences and logical connectives, Quine contends, translation is radically indeterminate.

Quine assumes that overt bodily behavior is the only relevant evidence for the field linguist's efforts (1990: 37–38; *see* **Behaviorism: Varieties**), and he allows that the radical translator might have access to the totality of such evidence – that competing translation manuals might "accord perfectly . . . with all dispositions to behavior on the part of all the speakers concerned" (1969a: 29). Therefore, his conclusion is not merely that I cannot *know* what the unique, correct translation of the speaker's utterances is, but that there is *no fact* about what their unique, correct translation is, because all the relevant evidence leaves the question unanswered. Moreover, Quine holds that the same considerations apply to understanding a speaker of my own language – even when that speaker is myself. "On deeper reflection, radical translation begins at home" (46). This is because first as a learner of my own language and then as an interpreter of my colinguists, I have access to no more evidence than the radical translator does. It follows that meaning itself is radically indeterminate.

Reactions to the Argument from Below

Critics have complained that behaviorism is false and, so, that Quine's argument fails to establish its conclusion (Chomsky, 1969); and that Quine, in spite of his avowed behaviorism (Quine, 1990: 37), helps himself to nonbehaviorist data about the speaker's *nonobservational* terms for assent and dissent (Hockney, 1975: 421; Glock, 2003: 178) and about the communicative exchange between speaker and radical translator (Glock, 2003: 175–182). Assent and dissent cannot simply be read from the speaker's behavior, and they cannot intelligibly be assigned stimulus-meanings. The only way that the field linguist can identify terms of assent and dissent is by assuming that the speaker *wants* to be interpreted and understood, that the speaker *understands* that she is being interpreted, that the speaker is familiar with performing the *speech acts* of *answering* a question and *correcting* the linguist's proffered usage, and so on. These assumptions are all ruled out by Quine's behaviorism.

Critics have also doubted whether there really could be entire alternative translation manuals of the sort Quine envisions. The contention, very roughly, is that the compensatory changes that Quine imagines making to other terms in one's translation manual in order to preserve one's favored translation of some given term would quickly come into conflict with the behavior of the speaker (Evans, 1975: 345–346) . If I translate *gavagai* as 'undetached rabbit part' instead of as 'rabbit,' for example, I may have to translate the speaker as allowing that an undetached rabbit part is white if and only if the entire rabbit is white (Miller, 1998: 139). But this has consequences for how I should translate the speaker's word for 'white' in other contexts, and I should not be surprised to discover that I want to translate her as affirming that snow is white, even when visible patches of it have been visited by local sled dogs.

The Argument from Above

Quine might try to meet some of these objections by appealing to the argument 'from above' (1970: 183). Physical theory, says Quine, is underdetermined by the available evidence. More than one set of physical hypotheses could be compatible with the totality of empirical evidence. However, even if we select a particular physical theory on pragmatic grounds, Quine contends, our linguistic theory will remain underdetermined relative to our physical theory – "even if we 'fix' the physics" (Putnam, 1978: 53), nonobservational meaning will remain underdetermined. Linguistic hypotheses are underdetermined by a set of *more basic* 'facts' that are themselves already underdetermined. It is this double underdetermination that distinguishes semantic indeterminacy from normal empirical underdetermination.

Reactions to the Argument from Above

It is not clear, however, that this second argument operates independently of the argument from below, for the only plausible reason for thinking that the linguistic data are doubly underdetermined with respect to physical theory seems to be that mere physical behavior and the observation-sentences it undergirds are more evidentially basic – the only evidence we have to go on – and rival systems of analytical hypotheses are compatible with that evidence (Kirk, 1986: 140–146; Miller, 1998: 147). Moreover, as Chomsky complains, even if linguistics remains underdetermined once the physics has been fixed, it is equally true that the physics remains underdetermined once the linguistics has been fixed (Chomsky, 1980: 20; Rorty, 1972: 451–453). Only if we grant physics a special privilege could there be a problem for the determinacy of meaning.

Quine's work has, nonetheless, been very influential in analytical philosophy of language, leading especially to the varieties of *interpretationalism*

defended by Donald Davidson and Daniel Dennett (*see* **Radical Interpretation, Translation and Interpretationalism**).

Indexicality: Philosophical Aspects

E Corazza, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

In most of our linguistic interchanges and thinking episodes, we rely on context to select items of discourse and items of thought. One often succeeds in talking and thinking about something because one is situated in a given context. In natural language we have tools whose specific function is to exploit the context of use in order to select an item in one's surroundings. If one says, 'It is raining here' while in London, one refers to London because one's utterance occurs in London. Were one to utter the same sentence in Paris, one would be referring to Paris. We can use the very same words and yet refer to very different items. When you use 'I', for instance, you refer to yourself, whereas when I use it, I refer to myself. We use the very same linguistic expression with the same conventional meaning. It is a matter of who uses it that determines *who* the referent is. Moreover, when Ivan, pointing to Jane, says 'she' or 'you,' he refers to Jane; Jane, however, cannot refer to herself using 'she' or 'you' (unless she is addressing an image of herself). If we change the context – the speaker, the time, the place – in which these expressions occur, we may end up with a different referent.

Among the expressions that may switch reference with a change in context, we have personal pronouns ('my', 'you', 'she', 'his', 'we'...), demonstrative pronouns ('this', 'that'), complex demonstratives ('this pencil', 'that brunette in the corner'...), adverbs ('today', 'yesterday', 'now', 'here'...), adjectives ('actual', 'present'), and possessive adjectives ('my pencil', 'their car'...).

These expressions have been termed, following Peirce, *indexicals*. Indexicals constitute the paradigm of context-sensitive expressions, i.e., those expressions that rely on the context of use to select an object of discourse. Reichenbach (Reichenbach, 1947) claimed that indexicals are *token reflexive*, for they can be defined in terms of the locution 'this token', where the latter (reflexively) self-refers to the very token used. So, 'I' can be defined in terms of 'the person who utters this token', 'now' in terms of 'the time at which this token is uttered', 'this pen' in terms of 'the pen indicated by a gesture

defended by Donald Davidson and Daniel Dennett (*see* **Radical Interpretation, Translation and Interpretationalism**).

Indexicality: Philosophical Aspects

E Corazza, University of Nottingham, Nottingham, UK

In most of our linguistic interchanges and thinking episodes, we rely on context to select items of discourse and items of thought. One often succeeds in talking and thinking about something because one is situated in a given context. In natural language we have tools whose specific function is to exploit the context of use in order to select an item in one's surroundings. If one says, 'It is raining here' while in London, one refers to London because one's utterance occurs in London. Were one to utter the same sentence in Paris, one would be referring to Paris. We can use the very same words and yet refer to very different items. When you use 'I', for instance, you refer to yourself, whereas when I use it, I refer to myself. We use the very same linguistic expression with the same conventional meaning. It is a matter of who uses it that determines *who* the referent is. Moreover, when Ivan, pointing to Jane, says 'she' or 'you,' he refers to Jane; Jane, however, cannot refer to herself using 'she' or 'you' (unless she is addressing an image of herself). If we change the context – the speaker, the time, the place – in which these expressions occur, we may end up with a different referent.

Among the expressions that may switch reference with a change in context, we have personal pronouns ('my', 'you', 'she', 'his', 'we'...), demonstrative pronouns ('this', 'that'), complex demonstratives ('this pencil', 'that brunette in the corner'...), adverbs ('today', 'yesterday', 'now', 'here'...), adjectives ('actual', 'present'), and possessive adjectives ('my pencil', 'their car'...).

These expressions have been termed, following Peirce, *indexicals*. Indexicals constitute the paradigm of context-sensitive expressions, i.e., those expressions that rely on the context of use to select an object of discourse. Reichenbach (Reichenbach, 1947) claimed that indexicals are *token reflexive*, for they can be defined in terms of the locution 'this token', where the latter (reflexively) self-refers to the very token used. So, 'I' can be defined in terms of 'the person who utters this token', 'now' in terms of 'the time at which this token is uttered', 'this pen' in terms of 'the pen indicated by a gesture

accompanying this token', etc. The reference of an indexical expression depends on its particular linguistic meaning: 'the utterer of this token' is the linguistic meaning (the *character* (Kaplan) or *role* (Perry)) of 'I', while 'the day in which this token is uttered' is the linguistic meaning of 'today', and so on. The meaning of an indexical can be viewed as a rule which one needs to master to use an indexical correctly. An indexical's linguistic meaning can be conceived as a function taking as its argument the context and giving as its value the referent/content (this is Kaplan's famous content/character distinction).

It is often the case, however, that the linguistic meaning of expressions such as 'this', 'that', 'she', etc., together with context, is not enough to select a referent. These expressions are often accompanied by a pointing gesture or demonstration, and the referent will be what the demonstration demonstrates. Kaplan (1977) distinguishes between *pure indexicals* ('I', 'now', 'today', . . .) and *demonstratives* ('this', 'she', . . .). The former, unlike the latter, do not need a demonstration – or *directing intention*, Kaplan (1989) – to secure the reference.

In their paradigmatic use, pure indexicals differ from demonstratives insofar as the latter, unlike the former, are perception based. When one says 'I', 'today', etc., one does not have to perceive herself or the relevant day to competently use and understand these expressions. To competently use and understand 'this', 'she', etc., one ought to perceive the referent or demonstratum. For this reason, when a pure indexical is involved, the context of reference fixing and the context of utterance cannot diverge: the reference of a pure indexical, unlike the reference of a demonstrative, cannot be fixed by a past perception.

Moreover, a demonstrative, unlike a pure indexical, can be a vacuous term. 'Today', 'I', etc., never miss the referent. Even if I do not know whether today is Monday or Tuesday and I am an amnesiac, when I say 'Today I am tired,' I refer to the relevant day and to myself. By contrast, if one says 'She is funny' while hallucinating, or 'This car is green' while pointing to a man, 'she' and 'this car' are vacuous.

In addition, pure indexicals cannot be coupled with sortal predicates, while 'this' and 'that' often are used to form complex demonstratives such as 'this *book*', 'that *water*'. Sortal predicates can be considered to be *universe narrowers* which, coupled with other contextual clues, help us to fix a reference. If one says 'This liquid is green' while pointing to a bottle, the sortal 'liquid' helps us to fix the liquid and not the bottle as the referent. Moreover, personal pronouns which work like demonstratives (e.g., 'she', 'he', 'we',) have a built-in or hidden sortal. 'She', unlike 'he', refers to a female, while 'we' usually refers to a plurality of people, of whom one will be the speaker.

Indexicals are generally conceived of as singular terms that contribute a referent to what is said. According to the *direct reference* view (from Kaplan and Perry), utterances containing indexicals express singular propositions, i.e., propositions whose constituents are the referents of the indexicals. As such, indexicals are usually characterized as expressions whose interpretation requires the identification of some element of the utterance context, as stipulated by their linguistic meaning. Thus, an utterance of 'I am tired' expresses a proposition containing the referent of the first person pronoun, and one understands it insofar as one knows to whom the term 'I' refers in the context in which it is uttered. The linguistic meaning governing the use of the indexical – such as 'the agent of the utterance' *qua* meaning of 'I', 'the day of the utterance' *qua* meaning of 'today' – does *not* feature as a constituent of the proposition expressed.

If indexical expressions are characterized as singular terms contributing their referents into what is said (i.e., the proposition expressed), adjectives such as 'local', 'distant', 'actual' – not to mention count nouns like '(a) foreigner', '(an) enemy', '(an) outsider', '(a) colleague' – would not fall into the same category, for they do not contribute a referent to the proposition expressed. Yet they are, plausibly, context-sensitive expressions. 'Local', 'foreign', and 'native' in 'A *local* bar is promoting *foreign* wine' and 'A *native* speaker should correct your essay' do not contribute a specific individual or individuals to the proposition expressed. Hence, they are not singular terms. It should be evident that context-sensitivity does not merely concern singular terms. It is worth distinguishing between indexicals *qua* singular terms, contributing their referents to the proposition expressed, and *contextuals qua* expressions which, though context-sensitive, are not singular terms. Adjectives such as 'tall', 'big', 'small', 'old', etc., also are context-sensitive, insofar as one is only tall/small/big/old . . . relative to a comparison class. Jon may be too short to play tennis and yet too tall to be a jockey, while Jane may be too old to join the army and too young to take early retirement. But see Cappelen and Lepore (2004) and Borg (2004) for the view that words such as 'tall', 'foreigner', 'old', and the like are not genuinely context sensitive.

Proper names, like indexicals, also contribute individuals into the proposition expressed. As such they are singular terms, too; yet they are not indexicals (but see Recanati, 1993 for a different view). Nouns such as 'Monday', 'February', and the like also seem to contribute specific individuals in the proposition

expressed. They are best viewed in the same light as count nouns, i.e., as nouns such as 'lemon', 'frog', and 'table' (see Corazza, 2004). As such, they can be used to build singular terms. This happens when they are coupled with an indexical expression such as 'this', 'next', 'last' and they contribute to complex demonstratives of the form 'next week', 'last Saturday', 'next Christmas'. This peculiarity parallels the way count nouns can participate in building complex demonstratives such as 'these lemons', 'that table', 'this pen'. (King, however, defends the view that complex demonstratives are quantified terms).

One of the major features of indexicals differentiating them from other referential expressions (e.g., proper names: 'Plato', 'Paris'; mass terms: 'silver', 'water', terms for species: 'frog', 'raspberry', and so on) is that they are usually used to make reference *in praesentia*. That is, use of an indexical exploits the presence of the referent. Usually in a communicative episode involving an indexical, the referent is in the perceptual field of the speaker and contextual clues are used to raise the referent to salience (see Smith, 1989; Sidelle, 1991; and Predelli, 1998 for a discussion of indexicals used to refer to objects not present, e.g., answering machines, post-it notes, etc.)

When indexicals are not used to make reference *in praesentia* they exploit a previously fixed reference. 'That boy' in '*That boy* we encountered yesterday was in trouble with the police' does not refer to someone present. In cases like this, the indexical makes reference *in absentia*. One can thus distinguish between the context of utterance and the context of reference fixing. In our example, the speaker and the hearer appeal to a past context to fix the reference. The gap between the two contexts would be bridged by memory. Another way to handle examples like this would be to argue that, in such cases, the indexical expression works like an anaphoric pronoun linked to a tacit initiator. In the sentence 'In 1834 Jane visited her parents, *now* two old, sick people,' 'now' does not refer to the time of the utterance. It refers to 1834. It does so because it is anaphorically linked to '1834', and, as such, it inherits its reference from it. A similar story could be told about 'that boy': it inherits its reference from a tacit initiator, i.e., an unpronounced NP which is nonetheless presupposed in the discourse situation. To stress this interpretation, consider the following exchange: Jane: 'It is raining'; Jon: 'Then I won't be there before tomorrow.' In saying 'It is raining,' Jane tacitly refers to the location she is in, say London. With 'there', Jon refers to the very same location and we can claim that he does so because 'there' works in an anaphoric way, inheriting its value from the tacit reference made by Jane.

Furthermore, indexicals differ from other referential expressions insofar as (in their paradigmatic use, at least) they cannot be deferential. While one often relies on the so-called division of linguistic labor when using non-indexical expressions (e.g., proper names or mass terms), one cannot depend on the same phenomenon when using an indexical. One can, for instance, competently use 'Feynman' or 'elm' even if one does not know who Feynman is and even if one is unable to tell an elm from a pine. Indeed, a blind person can utter 'that vase' when she has been told that there is a vase in front of her. In these uses the reference is fixed by someone else (it is deferentially fixed). However, these are far from being the paradigmatic uses of an indexical such as 'that/this'. In their paradigmatic uses, they refer to something the user is perceptually aware of. This difference between indexicals and other terms parallels the fact that when using proper names, mass terms, and the like, context is in play before the name is used. As Perry suggests, we often use context to disambiguate a mark or noise (e.g., 'bank', or 'Socrates' used either as a tag for the philosopher or for the Brazilian football player). These are pre-semantic uses of context. With indexicals, though, context is used semantically. It remains relevant after the language, words, and meaning all are known; the meaning directs us to certain aspects of context. This distinction reflects the fact that proper names, mass terms, etc., unlike indexicals, contribute to building context-free (eternal) sentences, that is, sentences that are true or false independently of the context in which they are used.

To sum up, philosophers have made several key claims about indexicals. They are tools whose function is to exploit context, and their hallmarks include not having a fixed referent, not being easily deployed *in absentia* of the thing referred to, not being used deferentially, and having context play (not just a pre-semantic role, i.e., determining which word has been used, but also) a semantic role. Philosphers have found that indexicals come in at least three varieties: pure indexicals ('I', 'now'), demonstratives ('this', 'she'), and contextuals ('foreign', 'local'). Key differences between the first and second variety are that, in contrast to pure indexicals, demonstratives are more perception-based, they may be vacuous, they can be combined with sortals, and directing intentions play a quite central role in their use. In addition to attracting the attention of philosophers, indexicals have also captured the interest of those working within the boundaries of cognitive science for several reasons (see, for instance, Pylyshyn, 2003 on how indexicality is relevant to the study of vision): they play crucial roles when dealing with such puzzling notions as the

nature of the self (see for instance the importance of 'I' in Descartes' cogito argument), the nature of perception, the nature of time, psychological pathologies, social interaction, and psychological development (see Corazza, 2004).

Indexicality in Peirce's Categories and Sign Typology

'Indexicality' is a feature of the 'index,' one of three types of signs identified by Charles S. Peirce, the other two being the 'icon' and 'symbol.'

According to Peirce, a sign is something that stands for something else, in some respect. It creates in the mind of the interpreter an equivalent sign, or perhaps a more developed sign, that is, an interpretant (2.228 – As is common in Peircean scholarship, quotes and citations will be identified by volume and paragraph number from Peirce [1931–1958]). That the sign stands for something in some respect means that it does not refer to the object in its entirety (dynamic object), but only to a part of it (immediate object). Furthermore, a sign subsists for Peirce according to the category of 'thirdness,' that is, it presupposes a triadic relation between itself, the object, and the interpretant thought, which is itself a sign. And given that it mediates between the interpretant sign and the object, the sign always plays the role of third party.

The icon is characterized by a relation of similarity between the sign and its object.

nature of the self (see for instance the importance of 'I' in Descartes' cogito argument), the nature of perception, the nature of time, psychological pathologies, social interaction, and psychological development (see Corazza, 2004).

Indexicality in Peirce's Categories and Sign Typology

'Indexicality' is a feature of the 'index,' one of three types of signs identified by Charles S. Peirce, the other two being the 'icon' and 'symbol.'

According to Peirce, a sign is something that stands for something else, in some respect. It creates in the mind of the interpreter an equivalent sign, or perhaps a more developed sign, that is, an interpretant (2.228 – As is common in Peircean scholarship, quotes and citations will be identified by volume and paragraph number from Peirce [1931–1958]). That the sign stands for something in some respect means that it does not refer to the object in its entirety (dynamic object), but only to a part of it (immediate object). Furthermore, a sign subsists for Peirce according to the category of 'thirdness,' that is, it presupposes a triadic relation between itself, the object, and the interpretant thought, which is itself a sign. And given that it mediates between the interpretant sign and the object, the sign always plays the role of third party.

The icon is characterized by a relation of similarity between the sign and its object.

The symbol is a sign "in consequence of a habit (which term I use as including a natural disposition)" (4.531). The symbol is never pure but contains varying degrees of indexicality and iconicity; similarly, as much as a sign may be characterized as an index or icon, it will always maintain the features of symbolicity: a sign to subsist as such always requires the mediation of an interpretant and recourse to a convention.

The index is a sign that signifies its object by a relation of contiguity, causality, or by some other physical and mechanical connection. This relation also depends on a *habitus* or convention: e.g., the relation between hearing a knock at the door and someone on the other side who wants to enter. Convention relates the knocking to the knocker, but contiguity/causality predominates to the point that we are surprised if we open the door and nobody enters. Types of index include: (1) 'symptoms,' medical, psychological, natural, or social phenomena (actual contiguity + actual causality; (2) 'clues,' natural phenomena, attitudes, and inclinations (presumed contiguity + nonactual causality); (3) 'traces,' physical or mental (nonactual contiguity + presumed causality). "An 'index,'" says Peirce, "is a sign which would, at once, lose the character which makes it a sign if its object were removed, but would not lose that character if there were no interpretant" (2.304).

Signs subsist in the dialectic between symbolicity, indexicality, and iconicity. The symbol is never pure but contains varying degrees of indexicality and iconicity; similarly, a sign that is prevalently indexical or iconic maintains the characteristics of symbolicity – it requires the mediation of an interpretant sign and recourse to a convention.

Symbolicity refers to the sign's conventional character, the relation of constriction by convention between a sign and its object established on the basis of a code, a law. To say it with Peirce: "I define a Symbol as a sign which is determined by its dynamic object only in the sense that it will be so interpreted. It thus depends either upon a convention, a habit, or a natural disposition of its interpretant, or of the field of its interpretant (that of which the interpretant is a determination)" (letter from Peirce to Welby, 12 October 1904, in Hardwick, 1977: 33).

Indexicality refers to the compulsory character of the sign, to the relation of cause and effect, of necessary contiguity between sign and object: "I define an Index as a sign determined by its dynamic object by virtue of being in a real relation to it" (Hardwick, 1977: 33). The index requires mediation by an interpretant sign and recourse to a convention. But in the case of the index, unlike symbols, the interpretant does not decide on the object. On the contrary, the relation between sign and object preexists with respect to interpretation, it is an objective relation and in fact conditions interpretation. The sign and that which it stands for are given together independently of the interpretant. Nonetheless, this independence does not exclude the necessity of recourse to a convention to organize the relation between sign and object as a sign relation.

Indexicality belongs to the category of 'secondness,' one of Peirce's three categories, the other two being 'firstness' and 'thirdness.'

- Firstness is the mode of being of that which is such as it is, positively and without reference to anything else.
- Secondness is the mode of being of that which is such as it is, with respect to a second but regardless of any third.
- Thirdness is the mode of being of that which is such as it is, in bringing a second and third into relation to each other (8.329).

Firstness (in-itselfness, originality), secondness (over-againstness, obsistence) and thirdness (in-betweenness, transuasion) are universal categories. Peirce's categories help to explain logicocognitive processes and therefore at once the formation of signs. Analyzed in terms of Peirce's typology of signs, firstness coincides with the sphere of iconicity. Something that presents itself as firstness, presence, 'suchness,' pure quality is characterized by the relation of similarity (1.356–1.358). Analyzed in terms of Peirce's typology of signs, thirdness coincides with the sphere of symbolicity. Together with the other two categories, thirdness guides and stimulates inquiry and therefore has a heuristic value. The inferential relation between premises and conclusion is based forever on mediation, that is, on thirdness.

Secondness is the category according to which something is considered relatively to or over against something else. It involves binarity, a relation of opposition or reaction. From the viewpoint of signs, secondness is connected with indexicality. The icon, which is governed by firstness, presents itself as an original sign, the symbol, which is governed by thirdness, as a transuasional sign, while the index, which is governed by secondness, is an obsistent sign (2.89–2.92).

Any sign may be taken as something in itself, or in relation to something else (its object), or as a go-between (mediating between object and interpretant). On the basis of this threefold consideration, Peirce establishes the following correspondences between his trichotomy of the categories (all his trichotomies contain thirdness insofar as they are trichotomies) and three other important trichotomies in his semiotic system: firstness: qualisign, icon, rheme; secondness:

sinsign, index, dicisign (or dicent sign); thirdness: legisign, symbol, argument (2.243). Symbolicity is the sign dimension that shares most in thirdness, because it is characterized by mediation (or in-betweenness), iconicity by firstness or immediacy (or in-itselfness), and indexicality by secondness (or over-againstness). The category of secondness, together with firstness and thirdness are the omnipresent categories of mind, sign, and reality (2.84–2.94).

On the level of the typology of signs, firstness, secondness, and thirdness correspond to iconicity, indexicality, and symbolicity; on the level of logic, they correspond to abduction, deduction, and induction; and on the level of ontology, to agapism, anancism, and tychism.

From the viewpoint of logic, inference regulated by secondness and indexicality corresponds to deduction (while inference regulated by firstness and iconicity corresponds to abduction, and inference regulated by thirdness and symbolicity corresponds to induction). In fact, in the case of an 'obsistent argument' or deduction, the conclusion is compelled to acknowledge that the facts stated in the premises, whether in one or both, could not be if the fact stated in the conclusion were not there (2.96).

Indexicality and Logic

From the viewpoint of ontology, of universal being, secondness, and in sign typology, indexicality is present in the law of 'anancasm' or necessity. According to Peirce, this necessity regulates the evolutionary development of the universe together with 'agapasm' (creative love, which corresponds to firstness) and 'tychasm' (causality, which corresponds to thirdness) (6.287–6.317).

To indexicality and respectively secondness or obsistence, a binary category, there corresponds a relation of relative alterity in which the terms of the relation depend on each other. Effective alterity, the possibility of something being-on-its-own-account, absolutely, *per se*, autonomously, presents itself as firstness, or orience, or originality, according to which something "**is what it is without reference to anything else** within it or without it, regardless of all force and of all reason" (2.85). An effective relation of alterity is not possible in terms of binarity, indexicality, secondness, obsistence. Relations of alterity are not possible in a system regulated exclusively by secondness, therefore, binarity, where an element exists only on the condition that it refer to another element and would not exist should this other element be negated. "Take, for example, a husband and wife. Here there is nothing but a real twoness; but it constitutes a reaction, in the sense that the husband makes the wife a wife in fact (not merely in some comparing thought); while the wife makes the husband a husband" (2.84).

In the succession deduction–induction–abduction, the degree of alterity increases. Says Peirce: "Abduction is the process of forming an explanatory hypothesis. It is the only logical operation which introduces any new idea; for induction does nothing but determine a value, and deduction merely evolves the necessary consequences of a pure hypothesis. Deduction proves that something **must** be; induction shows that something **actually is** operative; abduction merely suggests that something **may be**" (5.172). Abduction is the inferential process by which the rule that explains the fact is hypothesized through a relation of similarity (iconic relation) to that fact. This rule that acts as the general premise may be taken from a field of discourse that is close to or distant from that to which the fact belongs, or it may be invented *ex novo*. If the conclusion is confirmed, it retroacts on the rule and convalidates it (ab- or retro-duction). Such a retroactive procedure makes abductive inference risky, exposing it to the possibility of error; at the same time, if the hypothesis is correct, the abduction is innovative, inventive, and sometimes even surprising.

Peirce connected indexicality and deduction:

> An Obsistent Argument, or **Deduction**, is an argument representing facts in the Premiss, such that when we come to represent them in a Diagram we find ourselves compelled to represent the fact stated in the Conclusion; so that the conclusion is drawn to recognize that, quite independently of whether it be recognized or not, the facts stated in the premisses are such as could not be if the fact stated in the conclusion were not there; that is to say, the Conclusion is drawn in acknowledgment that the facts stated in the Premiss constitute an Index of the fact which it is thus compelled to acnowledge (2.96).

Indexicality and Dialogicality

In inference, the relation between the premises and conclusion may be considered in terms of dialogue between 'interpreted signs' and 'interpretant signs' (Ponzio, 1990: 49–61). The degree of dialogicality and alterity is low in induction – where the relation between premises and conclusion is determined by habit and is of the symbolic type – and in deduction – where the conclusion is a necessary derivation from the premises in a relation of the indexical type. To be precise, the degree of dialogicality in the relation between interpreted (premises) and interpretant (conclusion) (an indexical relation) is minimal in deduction: once the premises are accepted the conclusion is compulsory. Induction (where the relation between

premises and conclusion is symbolic) is also characterized by unilinear inferential processes: identity and repetition dominate, but the relation between premises and conclusion is no longer compulsory. Instead, in abduction the relation between the argumentative parts is dialogic in a substantial sense. The relation between premises and conclusion is predominantly iconic, therefore a relation of reciprocal autonomy. Consequently, abductive inference can generate sign processes at high levels of dialogicality and otherness, therefore responses that are risky, inventive, and creative with a minimal margin for convention or symbolicity and mechanical necessity or indexicality.

An approach to indexicality in terms of dialogue has its source in a theoretical framework that may be identified as Peircean-Bakhtinian (from Russian philosopher Mikhail Bakhtin), and its basis in the distinction between 'formal dialogicality' (which refers to the fact that a text is enacted or represented in the 'form of a dialogue') and 'substantial dialogicality' (which concerns the 'degree of dialogicality' in a given text, whether formally a dialogue or not). These two concepts of dialogicality do not necessarily coincide: a formal dialogue does not necessarily imply substantial dialogue, while the latter does not necessarily take the form of a dialogue. Signs and arguments are formally dialogical as the result of a dialogue between interpreteds and interpretants, according to varying degrees of dialogicality. From a semiotic perspective, the relationship between interpreteds and interpretants results in signs which – on a scale ranging from a maximum degree of monologism to a maximum degree of dialogism, otherness, and creativity – may be (prevalently) indexical, or symbolic, or iconic; from the perspective of logic, the relationship between interpreteds (premise) and interpretants (conclusion) results in arguments or inferences and is of the deductive, inductive or abductive type. The varying balance in indexicality, symbolicity, and iconicity in any given sign situation, whether formally a dialogue or not, involves variations in the degree of otherness and dialogicality regulating the relationship between the interpreted (premise) and interpretant (conclusion) of an argument: therefore, argumentative value may also be measured in terms of the degree of substantial dialogicality (Ponzio, 1990: 215–232).

Theory of Indexicality in a Peircean Semiotic Framework

Peirce's recognition of the need for the index may be connected with his interest in Duns Scotus's realism and the notion of *aecceitas* (thisness), which indicates the single thing in contrast to universality, i.e., the reality of actuality or secondness: "hic and nunc," Peirce observes, "is the phrase perpetually in the mouth of Duns Scotus" (*CP* 1.459). "The index has the being of present experience" (4.447) of *hic* and *nunc*. An index "is a sign which refers to the Object it denotes by virtue of being really affected by that Object" (*CP* 2.248), where the word "really" resonates to Scotus's doctrine of *realitas et realitas* (Sebeok, 2001: 87). To demonstrate the centrality of indexicality in Peircean semiotics, Thomas A. Sebeok (2001) observed that Peirce contended that no matter of fact can be stated without the use of a sign serving as an index, because 'designators' compose one of the main classes of indexes and because designation is "absolutely indispensable both to communication and to thought. No assertion has any meaning unless there is some designation to show whether the universe of reality or what universe of fiction is referred to" (8.368). Indexes "whose relation to their objects consists in a correspondence in fact ... direct the attention to their objects by blind compulsion" (1.558). Deictics of various kinds, including tenses, that offer the most clear examples of indexicality.

Indexicality, iconicity, and symbolicity are three complementary rather than antagonistic categories. Peirce returned repeatedly to his sign typology. By 1906, he had classified 66 different types of signs. However, the most important in all his reflections on signs was a trichotomy formulated in relation to his original typology and presented in an article of 1867, 'On a new list of categories' (1.545–1.559). With this trichotomy, Peirce identified three types of signs: icons, indexes, and symbols. Sebeok evidenced that all three are present in nonhuman semiosis as well (for a synthesis of the comparison between the human world and the world of other animals relatively to this typology, see Sebeok, 2001). From the perspective of sign types, there is no difference between human and nonhuman semiosis. In the light of Sebeok's research, it is now clear that icons, indexes, and symbols are present both in languages (which are human) and in nonlanguages.

As observes Sebeok elaborating on Peirce's typology, not signs but sign aspects are the object of classification. The hybrid character of the sign should now be obvious with respect to its distinction into symbol, index, and icon. The Peircean conception of the relation between symbol, icon, and index has very often been misunderstood. In fact, these terms were thought to denote three clearly distinguished and different types of sign, each with characteristics so specific as to exclude the other two. Now we know that signs that are exclusively symbols, icons, or indexes do not exist in the real world. Furthermore (and what most interests us here) in Peirce's theory, the symbol is a

mere abstraction. It is never conceived as existing as a pure symbol but is always more or less mixed with iconicity and indexicality, or to say it with Peirce, it is always more or less 'degenerate.'

This denotion implies that more than being signs in their own right, the icon and index represent different levels in 'degeneracy of the symbol.' The symbol is not purely a symbol but almost always takes the characteristics of either the icon or index. The symbol may be represented iconically as a body in a state of unstable equilibrium, in which the stabilizing symbolic force is counteracted by iconic and indexical forces. But this image establishes a relation of contrast between symbol, index, and icon, when in fact they are not separate or distinct, nor are they in a relation of opposition.

Otherwise, with respect to the symbol, we would have signs that are purely icons or purely indexes and not simultaneously symbols; or symbols with no traces of iconicity or indexicality. Perhaps the image that best accounts for the relation of the symbol to the index and icon is that of a filigreed transparency with uneven traces of iconicity and indexicality, as opposed to pure transparency.

Indexicality is at the core of the symbol, given that the symbol depends on the interpretant as a result of its relation to the object. This relationship is what makes a sign a symbol. This result means that transuasion, which characterizes the symbol as a transuasional sign, is considered in its obsistent aspect (2.92), and that the index is an obsistent sign. On the other hand, insofar as it is determined by the instances of what it denotes and being a general type of law, the symbol entails indexicality. In the sign considered as a symbol, identity hinges upon the alterity of the sign, which is determined by mediation of the interpretant, so that, insofar as it is a symbol, "a sign is something by knowing which we know something more" (8.332). However, this expansion is so because the sign is not only a symbol, or better, the very fact of being a symbol involves iconicity and indexicality given that thirdness, the mode of existence of the symbol, presupposes firstness and secondness or originality and obsistence, which correspond respectively to the icon and index.

From the viewpoint of its relation to the object, the sign is a symbol insofar as it involves the mediation of an interpretant; from the viewpoint of its relation to the interpretant, the sign-symbol is an Argument. This statement is true if the sign-symbol distinctly represents the interpretant that it determines as its Conclusion through a proposition that forms its Premise, or more generally, its premises (2.95). Depending on the type of sign relation established in the argument between premises and conclusion, three kinds of arguments are possible: Deduction, Induction, and Abduction. Though differentiated, all three belong to the sphere of the symbolic and are of the transuasional order.

Peirce used the term 'Transuasional logic' to indicate the doctrine of the general conditions of determination of the interpretant (the conclusion) through propositions acting as premises (2.93). But three types of arguments are possible because they do not belong to the sphere of the symbolic alone. This means that not only the category of Transuasion comes into play but also that of Originality and Obsistence (2.84–2.96). In Peirce, the term Symbol indicates the genuine Sign obtained by abstracting from the two levels of 'degeneracy' of the sign. These are: the minor level – that of the Index; and the major level – that of the Icon. In the Symbol or genuine Sign, signification depends on the relation to the interpretant, whereas in the Index and Icon the capacity to signify is relatively autonomous with respect to the relation to the interpretant (2.92).

By virtue of the relation between icon, index, and symbol – a relation neither of autonomy and indifference nor of opposition, but rather of reciprocal implication – the sign is at once identical to itself and other.

The relation of implication changes in balance depending on whether the iconic, symbolic, or indexical aspect dominates, which is determined by the type of semiosis in course. All signs are symbols to the extent that they signify through mediation of an interpretant, but precisely because of such mediation they are not symbols alone.

In Peirce's semiotics, symbols, indexes, and icons overlap in such a way that if the symbol were purely symbolic, the relation between premises and the conclusion in the argument would paradoxically be indexical and not symbolic, and would not, in fact, give rise to a transuasive argument or induction. The latter presupposes a hypothesis resulting from a preceding abduction that implies iconicity (2.96). Let us suppose that the relation between premises and conclusion is purely analytical and is wholly contained within the symbolic universe, the conventional/arbitrary, the Law; in other words, let us suppose that the relation between the symbol and interpretant is of mere identity. In this case, the relation between premises and conclusion is deductive and as a constrictive argument, it is endowed with the character of indexicality.

Mutual complicity between symbol, icon, and index should now be obvious. These three different shades of the sign are in turn implied in the cognitive

process. This implication means that they are at once categories of logic and semiotics (Ponzio, 1990: 197–214).

Indexical Types of Verbal and Nonverbal Signs and Signals

The main types of indexical signs include: (1) symptoms, (2) clues, and (3) traces. Let us consider them in detail.

In the case of the symptom, the relation of the interpretant to the interpreted is of contiguity and causality: blotchy skin (interpreted), liver disease (interpretant); smoke (interpreted), fire (interpretant).

In the case of the clue, the relation of the interpretant to the interpreted is of causality (but not given in present time), on the basis of a presumed relation of contiguity: a cloudy sky as a sign that it will rain; a bloodstain on a glove as a clue that the owner is the assassin.

In the case of the trace, the relation of the interpretant to the interpreted is of contiguity (not given in present time) on the basis of a presumed relation of causality: a footstep is interpreted as the trace of a man or animal; a phobia as the trace of a certain event.

Symptoms, clues, and traces are not produced as the repetition of a pre-established interpretant of identification: they are not the result of a coding process, nor are they endowed with communicative intentionality (otherwise they would be signals: smoke used to signal one's presence or to transmit messages; footsteps left expressly by a person to signal his or her trajectory). However, these signs are interpretable because of their typicality, that is, they are already known, they have already been seen, and they repeat certain distinctive features. A preliminary moment of identification or recognition is also necessary: a footstep repeats certain distinctive features that characterize it as the imprint left by an animal, a man's or woman's shoe, a bare foot; if left by an animal, it may be characteristic of a horse (whether shod or not), a deer, etc. Similarly, a certain somatic fact appears as a symptom insofar as it repeats characteristics that identify it as that particular symptom and that link it to pathological state; in the same way, clouds mean rain if they are identified as that certain type of cloud that carries rain.

Thus traces, symptoms, and clues, also, have an identification interpretant that is determined on the basis of one's own experience or of others, and is established on the basis of a given tradition or social practice.

Similarly to signals, the relation between interpreted and interpretant is fixed on the basis of a law: in fact, handbooks are available for identification of given types of symptoms or clues or traces on the basis of specific distinctive features. A handbook of medical symptomatology or hunting are two such examples. By consulting handbooks as though they were signal codes or language dictionaries, specific traces, symptoms, or clues may be decoded even when one has no previous direct experience of them.

In some cases, symptoms, clues, or traces are produced intentionally and are predetermined by the identification interpretant in the course of their very production. In such cases, they function as signals, even if masked as symptoms, clues, or traces. An actor who recites rage or fear, a person who pretends to be moved, feigns illness, leaves footprints on the ground so as to be followed (e.g., to set a trap), or to divert the pursuer, intentionally produces symptoms, clues, and traces according to distinctive features foreseen by the identification interpretant. Therefore, contrary to what the interpreter believes, the latter does not come into play exclusively when such features are being decoded (Ponzio, 1990: 44–36).

In signals disguised as symptoms, clues, or traces, the success of pretence depends on the fact that these signs remain distinct from signals, that is, they appear to be uncoded and devoid of an identification interpretant produced intentionally by a sender: they must not seem characterized by the identification interpretant 'at the source,' but only when they are actually being read and decoded. Thus, those cases in which symptoms, clues, and traces are signals highlight the distinction between such signs and signals as well as the distinction between the latter and verbal signs in their signal dimension rather than generally invalidating this distinction, that is, between the signs in question and signals.

Besides acting as signals, verbal signs, when such aspects as those mentioned in the preceding paragraph come into play, may also function as symptoms, clues, or traces: without speaker or writer intention, a piece of discourse, whether written or oral, may be read as indicating a specific social status or place of origin, it may betray impatience or uneasiness, foresee a certain development in the relation between interlocutors, indicate that the person speaking is in a hurry to conclude the conversation, etc. We qualify verbal signs that are symptoms, clues and traces as paraverbal signs.

Therefore, verbal signs have dual signality: as far as they are intentional, they are also signals, and as far as they are unintentional, they may also be symptoms, clues, and traces. Dual signality in verbal signs

becomes triple when unintentionality is recited, calculated, or feigned, that is, when that which seems to be a symptom, clue, or trace in the verbal sign is, in reality, a disguised signal.

Indexicality in Verbal Language

Indexicality is discussed by Peirce to solve the problem of the connection between verbal language and referents in the real world. Verbal language is characterized by conventionality and 'diagrammatization.' Diagrammatization makes verbal language a 'sort of algebra'; consequently, it seems to be a sphere apart, separate from its objects. But thanks to indexicality, that is, to an association of contiguity, verbal language is not reducible to an algebric system.

Indexicality enables language to pass from the level of diagrammatization to the level of application of its diagrams.

The relation between the phonia *book*, the object *book*, and the graphia *book* is 'conventional': however, traces of indexicality are also present, owing to the relation of continguity established between phonia and object, and phonia and graphia. In this case, continguity would seem to be established 'by convention.' But once this convention has been learned, it is a bond and continues to subsist thanks to the fact that the name and the object or the phonia and the graphia of the same word are given in a relation of continuity (Ponzio, 1990: 37–43).

Jakobson studies the indexical factor in verbal language in 'Shifters, verbal categories and the Russian verb' (1971 [1957]). The indexical function in verbal signs is carried out by a special class of grammatical units he calls 'shifters.' As characterized by Jakobson, shifters are 'symbol-indexes' because their dominant aspect is given in the combination of indexicality with conventionality.

An example of shifters is the personal pronoun. On one hand, *I* is conventional because we can only know what it means if we know the convention on the basis of which we interpret it as referring to its object under some aspect (a person considered under the aspect of speaking subject) and therefore as situated on the same interpretive trajectory as *ego*, *je* and *moi*, *ich*, *io*, etc. From this point of view, the sign *I* is a symbol. On the other hand, in order to refer to its object, that is, to the speaker, it must be in an 'existential relationship' with it. Therefore, *I* is also an index. The personal pronouns *I* and *you* may be interpreted as referring **alternatively to the same object**, according to whether it carries out the function of 'speaking subject' or 'subject spoken to.' This multiplicity is possible on the basis of a convention and at once on the basis of the fact of functioning as an index in the literal sense of a pointing finger.

Indexicality plays a fundamental role in verbal language. As Sebeok observed (1991: 128–143), Peirce highly valued the function of shifters owing to the connection between verbal language and its referents. Designations – exemplified by the various types of deixis, including verbal tenses – said Peirce:

> . . . are absolutely indispensable both to communication and to thought. No assertion has any meaning unless there is some designation to show whether the universe of reality or what universe of fiction is referred to. (8.368, note 23)

Two texts by Peirce on 'indexicality' in verbal language seem particularly significant, a paper of 1892 and another of 1893 (respectively in the third and fourth volumes of *Collected papers*). Peirce considers the problem of indexicality as part of his quest to solve the problem of how verbal language, characterized by diagrammatization, which makes it like algebra, is able to connect up with its referents. This connection is only possible, says Peirce, thanks to indexicality, that is to say, association of continguity:

> It is not the language alone, with its mere associations of similarity, but the language taken in connection with the auditor's own experiential associations of contiguity which determines for him what house is meant. It is requisite then, in order to show what we are talking or writing about, to put the hearer's or reader's mind into real, active connection with the concatenation of experience or of fiction with which we are dealing, and, further to draw his attention to, and identify, a certain number of particular points in such concatenation. (3.419)

The function of indexicality is to make language pass from the level of diagrammatization to the level of application of its diagrams. The recurrent distinction between subjects and predicates of propositions, implies the distinction, says Peirce, between the indicative part of discourse and what it affirms, questions, or commands about it.

Indicatives assert nothing (2.291). They only serve to draw attention to something, and if compared to verbs, they would be considered as imperatives, such as *be careful*, *look there*. Words like *this* or *that* "have a direct, forceful action upon the nervous system, and compel the hearer to look about him," says Peirce, "and so they, more than ordinary words, contribute towards indicating what the speech is about." Concerning the term 'pronouns' used for such words as *this* or *that*, Peirce observes that nouns would be more appropriately designated as

"pro-demonstratives" (3.419), as substitutes of indicators, that is deictics.

Terms like *this* or *that* are indexes with the function of drawing attention to what one means no differently from the expression *attention!* or similar cries. Terms like *this* or *that* refer to other words in written discourse; in this case, their function is no different from the relative pronouns *who* or *which*, etc., nor from use of the letters of the alphabet to indicate the issue in question in a text (naturally on the understanding that similar letters stand for the same thing). These terms continue to function as indexes that "de-algebrize" language (2.287).

"A possessive pronoun," said Peirce, "is an index in two senses": in the sense that it indicates the possessor, and in the sense that it denotes the thing possessed.

Peirce attributed the character of indexicality to indefinite pronouns such as *any*, *every*, *all*, *none*, *whoever*, etc., which he called 'universal selectives'; and to indefinite pronouns like *some*, *something*, *somebody*, which he called 'particular selectives.'

Furthermore, adverbs of place and time, etc., must also be taken into consideration in relation to indexicality, together with such expressions as *the first*, *the last*, *the seventh*, *the first part*, etc., and prepositions and prepositional phrases such as *above*, *below*, *to the right of*, *to the left of*, etc. (2.289–2.290).

Peirce also observes that while terms that carry out an iconic function in discourse – similarity, quality, etc. – may be described, those, instead, with the function of index escape description.

Given that it is the ultimate condition of semiosis and communication, indexicality may be considered as the extreme limit of semiotic description.

An historical perspective on indexing shows an important tie between human indexing and ease of retrieval of information. Two early forms of indexing, requiring different skills from a human indexer, were back-of-the-book indexing, which allowed a reader to search for specific information within a book, and subject heading assignment, which was used to classify a book within a library system. Most automatic indexing research focuses on documents in electronic form and assumes indexing at a document-level granularity with a strong emphasis on its purpose in document retrieval. Natural language indexing exports part of a document's content into a separate file to serve as a text surrogate for retrieval purposes. Controlled vocabulary indexing creates an index file by assigning to a document terms from an external lexical resource. Both approaches have their advantages and limitations. In information retrieval, the problem of matching query terms and document index terms is largely due to the fact that one idea can be expressed in many different ways: the paraphrase problem. In a Web environment, terabytes of information amplify this paraphrase problem and render it multilingual. As longer documents appear on the Web, interactive forms of indexing should be investigated not only to retrieve documents but to browse efficiently through them. Although indexing has been much studied, as the large body of literature on both human and automatic indexing acknowledges, much work remains ahead to handle the constant growth of electronic information.

An historical perspective on indexing shows an important tie between human indexing and ease of retrieval of information. Two early forms of indexing, requiring different skills from a human indexer, were back-of-the-book indexing, which allowed a reader to search for specific information within a book, and subject heading assignment, which was used to classify a book within a library system. Most automatic indexing research focuses on documents in electronic form and assumes indexing at a document-level granularity with a strong emphasis on its purpose in document retrieval. Natural language indexing exports part of a document's content into a separate file to serve as a text surrogate for retrieval purposes. Controlled vocabulary indexing creates an index file by assigning to a document terms from an external lexical resource. Both approaches have their advantages and limitations. In information retrieval, the problem of matching query terms and document index terms is largely due to the fact that one idea can be expressed in many different ways: the paraphrase problem. In a Web environment, terabytes of information amplify this paraphrase problem and render it multilingual. As longer documents appear on the Web, interactive forms of indexing should be investigated not only to retrieve documents but to browse efficiently through them. Although indexing has been much studied, as the large body of literature on both human and automatic indexing acknowledges, much work remains ahead to handle the constant growth of electronic information.

Natural Language Indexing

Natural language indexing, also known as free-term indexing, or extraction indexing, aims first at finding terms within a document that would best characterize its content and second at storing these terms to allow easy retrieval of the original document. Early work, presented at the first International Conference of Scientific Information in 1959, pioneered the field with a strong computational flavor by exploring storage strategies. Herbert Ohlman presented his permutation index, allowing each non-stop-word of a title to serve as an index, and independently, Hans Peter Luhn presented an automatic version of the Key Word in Context (KWIC) idea, which he had developed at IBM. Present-day research on automatic indexing takes a strong linguistic flavor, focusing on methods to extract good index terms from a document.

The Natural language indexing process consists principally of the following three steps (Salton, 1989): (1) find individual words in the text; (2) remove function words and highly frequent words; and (3) compute a weight for each remaining word according to how well it characterizes the text. Even the first two steps, seemingly easy, present challenges. For example, periods are not always good word delimiters as they might occur within abbreviations, and filtering 'a' as a function word is problematic when it takes a semantic value, as in *vitamin A* (Anderson and Pérez-Carballo, 2001b).

The first step presents a further challenge as the notion that index terms should be words is debatable. Many researchers rather suggest the extraction of phrases to provide specific index terms. More complex approaches using tagging or even shallow parsing are necessary to extract phrases. Phrases carry more semantic meaning than individual words and can improve the specificity of the indexing language by being less ambiguous (Moens, 2000). Unfortunately, phrases have one main problem: their forms vary and many variants exist to express the same concept. As much as stemming is used on words to conflate variations into a single index term, some process of normalization would be needed to find phrase variants and assign them to a single concept.

The third step of assigning a weight to each term is both difficult and debatable, as even human indexers do not agree on which index terms best represent a document. The notion of discrimination value (DV) of a term, as introduced by Salton (1981), is the difference between the document collection density when this term is used as an index term and when it is not. The degree of specificity of a term is an indicator of its discrimination value. General terms tend to be assigned to many documents and create a compressed document space where it seems as if all documents are similar. On the other hand, specific terms tend to create a uniformly distributed document collection, as if all documents were uniquely characterized. The solution lies in a middle ground where a good index term has an average specificity with the capability of clustering the document space, where clusters are documents likely to be considered similar by a search user.

The weight w_{ij} of an index term j in document i of a collection of n documents should represent its DV, but as this is very computationally-intensive to calculate, it is approximated mainly by two factors: term frequency, tf_{ij} (frequency of term j in document i), and inverse document frequency, idf_j, where $idf_j = -\log(n/df_j)$. (frequency of term j in all n documents) (Salton, 1981). Most equations found in the literature on statistical approaches to indexing present different combinations of these two factors. As examples, here are four variations for w_{ij}:

$$w_{ij} = 1 \tag{1}$$

$$w_{ij} = tf_{ij} \tag{2}$$

$$w_{ij} = tf_{ij} \times \log\left[\frac{(n - df_j)}{df_j}\right] \tag{3}$$

$$w_{ij} = (\log(tf_{ij}) + 1) \times idf_j. \tag{4}$$

In addition to frequency-related features, some heuristics about text structure can be devised. Words found in the title or at the beginning of each paragraph can be considered as deserving extra weight. Certain types of documents might even have specific structures to be explored. For example, in lecture transcripts, words of sentences containing a summarizing or presentation statement could be attributed a higher weight as could words around a citation in a scientific article, as we can assume these sentences introduce important ideas.

The weight assignment process is very difficult to evaluate. In general, natural language indexing is evaluated in an extrinsic manner, meaning indirectly via an information retrieval (IR) task. Isolating the index performance from the entire IR system's performance is therefore difficult. IR is evaluated via precision and recall to determine whether the documents retrieved are actually relevant ones (precision) and whether relevant documents as established by a particular authority (human judges) are actually retrieved (recall). As index term discrimination value has been linked to recall and precision (Salton, 1981), the IR evaluation should be indicative of the effectiveness of the index terms in the process.

Controlled Vocabulary Indexing

Controlled vocabulary indexing, also called assignment indexing, selects a set of index terms from an external resource to be assigned to a document. Different external resources exist, displaying different levels of granularity and types of organization. Subject headings, most often used in human indexing, are organized in a classification hierarchy. The National Library of Medicine's Medical Subject Headings and Unified Medical Language System, as well as the Library of Congress Subject Headings, are examples of such repositories. A finer grain resource with more complex relations among its terms is a thesaurus. Such relations include broader term (*dog – animal*), narrower term (*dog – poodle*), and related term (*dog – canine*). A fundamental difference exists between thesauri and subject headings as the latter offers an *a priori* attempt to represent the whole of the structure of the universe and the former, in contrast, is usually derived from existing and growing collections of books and journals in a subject discipline. An even more rigid *a priori* established hierarchical system is the classification codes. For example, Melvil Dewey, at the end of the 19th century, began with 10 classes of knowledge and developed the Dewey Decimal Classification (DDC) as a purely hierarchical classification system representing all human knowledge. The DDC is still used extensively in current-day library systems. The largest problem is the mutual exclusivity implicit in every hierarchical classification scheme. In that respect, thesauri are more flexible as they allow interconnections between classes.

Terms in a thesaurus, subject headings, or classification codes can all be seen as labels that an automatic process would attempt to assign to a document. Assignment indexing is perceived from the natural language processing community as a text classification task, sometimes further associated with text filtering and routing. Although rule-based approaches have been investigated (for a success story of rule-based classification of Reuters news stories, see Hayes and Weinstein (1991)), these approaches are quite time-consuming and currently machine-learning approaches are popular alternatives to text classification. In a supervised setting, classification rules are learned from a labeled training set and can be used to infer classes for texts from a test set. An overview of classification techniques (statistical, learning of rules and trees, and neural networks) as well as feature selection for text classification can be found in Moens (2000). Early insight on thesaurus construction, indexing, and classification can be found in Sparck Jones (1971).

In contrast to natural language indexing, controlled vocabulary indexing tends to be evaluated in an intrinsic way, by comparing directly the labels automatically assigned with those assigned by human indexers. This, of course, assumes that human indexers are correct. Unfortunately, the literature shows experiments where much disagreement exists not only among judges but also between multiple instances of indexing the same document by the same judge. Fugmann (1999) suggested predictability of an index term as a good indicator of its relevance, since many terms can be near-synonyms or paraphrases of the same concept and therefore we cannot assume that two indexers would choose the same one (consistency), but we can assume that given one, we can predict the other (predictability). This notion is yet to be seen in automatic indexing evaluation.

Even beyond the problem of synonymy, some authors have argued that objective indexing does not exist and that any indexing task is to be performed from a point of view. For example, Mother Goose rhymes could be important for research specialists from the perspectives of fairy tales, myths, English literature, English history, and psychoanalysis (Harter, 1986). These problems are less likely to occur when many categories can be assigned to a text.

Indexing as Filling the Conceptual Gap in Information Search

Search uncertainty is defined as the latitude that users have in choosing search terms, also sometimes referred to as the paraphrase problem. The probability is small (experiments reported in the literature estimate it at 20%) that two people will use the same term (symbol) to describe the same idea (concept). Indexing relying on symbols, not concepts, is therefore problematic (see Riloff and Lehnert (1994) for further analysis). Synonymy (many symbols for the same concept) impacts on recall performance of the information retrieval task as many texts are not retrieved because they express the query's idea using different symbols. On the other hand, polysemy (many concepts for the same symbol) impacts on precision as it will cause the retrieval of many irrelevant documents discussing a different sense of a query symbol.

Synonymy and Normalization

Normalization and expansion are two opposite solutions to the same synonymy problem. Either a query term is the starting point from which an expansion occurs to find all its synonyms in the hope that one of them will be present in a text or all term variants

found in a text are merged into a single normalized term to which the query term is also matched. Controlled vocabulary indexing, discussed above, is a form of normalization.

Unfortunately, resources that represent particular document collections well are not always available nor are they always constructed at the desired level of generality. To attempt normalization or expansion without an external resource, one must explore methods for automatic construction of thesaurus (Chen *et al.*, 1998). Such construction is done on a particular collection to try to establish relations between words. Thesaural relations of narrower, broader, and related terms are then approximated via similarity measures based on word co-occurrence in text (see Salton and Lesk (1968) for a comparison of different measures in early work). There is currently much interest in research on corpus-based statistical estimations of word similarity.

With a similar intent to reduce space but using a different approach, latent semantic analysis (Deerwester *et al.*, 1990) addresses the concept–symbol problem by attempting to find the underlying semantic structure of the term–document relation. In this particular case, the space reduction does not lead to specific identifiable concepts, but to unlabeled distributed concepts.

The automatic methods above lead to unnamed relations of similarity between terms. A different approach would be the semiautomatic construction of a terminological database in which variants are grouped by concept with explicit relations of hyperonymy, meronymy, and synonymy between concepts. This idea is further discussed below, but research has not yet provided fully automatic approaches for such construction.

Polysemy and Interactive Approach

Polysemy, in the context of document retrieval, is quite problematic. Queries are usually short, one or two words, and therefore do not provide sufficient context to attempt any word sense disambiguation strategy. Research efforts are then pushed toward the interaction between the user and the large set of documents retrieved. Document clustering, by grouping related documents, almost *de facto* performs word sense disambiguation as documents within a single cluster are likely to promote the same sense of a word. Indexing plays an important role in document clustering as document similarity can be established based on documents' index term vectors. Other features, such as citations in scientific articles, have also been used for document clustering. Citation indexing (Giles *et al.*, 1998) assumes that articles all citing a particular article of interest will have enough in common to be clustered. Co-citation indexing (Anderson and Pérez-Carballo, 2001b) establishes a similarity between two documents if a number of articles refer to them jointly.

Many clustering strategies exist. A good review of hierarchical document clustering can be found in Willett (1988).

Once documents are clustered, interactive topic maps allow users to navigate from one document to another to find related documents to a single query. A topic map helps the user through a conceptual space as it shows documents with graphical distance proportional to their real distance.

User interaction can also be used to identify relevant and nonrelevant documents. It is likely that nonrelevant documents include senses of the query term that are not of interest. Relevance feedback promotes constant re-indexing as weights of more promising terms contained in the relevant documents can be increased. This should indirectly lead to finding more appropriate documents from the user's point of view. It is an interesting way of addressing the problem of objective indexing mentioned above, with an iterative process from objective to subjective.

Not only can documents be clustered, but index terms can be clustered and shown graphically to users to help them refine their query. A thesaural organization of index terms can allow a user to find more-general or more-specific terms to enlarge or narrow the query. This idea, taken to its limit, proposes a prenormalization step and constrains the user to a menu-based search with a limited fixed set of index terms. A middle ground might be a conceptual indexing approach (Woods, 1997), which automatically establishes a taxonomy of terms found in the document collection. This taxonomy can then be used to support browsing and navigation in conceptual space. It escapes the limitations of traditional library classification hierarchies by allowing conceptual categories to have multiple parent categories. An interesting feature is that it allows the automatic location of the most specific concepts that subsume an input query term. This conceptual indexing is meant to be used within an interactive browser focusing on the conceptual neighborhood of an input request.

Web Indexing

Most Web page indexing is based on full text indexing, meaning that all words (with the exception of stop words) found in a document serve as index terms. Weighing approaches dependent on inverse document frequency (Salton, 1981) are not applicable in a Web environment since the full collection is

not accessible. Neither linguistic nor statistical approaches are much in use. On the other hand, given the nature of the Web and its high content of proper nouns, sets of heuristics (rules) could be developed for particular types of knowledge to be extracted, such as company names or proper names (see Moens (2000)).

Future Web indexing must investigate Web organization through the conceptual (rather than symbolic) content of its pages, as well as through its hyperlinks. Investigations are foreseen in information value estimation, document content redundancy evaluation, semantic tagging, and categorization and organization of documents. The Semantic Web is a step in that direction, as it promotes semantic meta-tagging of information. Solutions to the polysemy and synonymy problems mentioned earlier via normalization and interactive browsing should be implemented. Variations on natural language indexing and controlled vocabulary indexing strategies should be investigated to respectively find specific terms present in the documents through specific queries and assign general category labels for general searches.

Furthermore, in a global village society, information retrieval (the main use of indexing) should become multilingual. This topic is much studied in international competitions on Cross-Language Information Retrieval. Although most approaches presented at these competitions rely on finding equivalent terms in different languages for a specific query term in one language, an alternative is to assign index terms in many languages to document collections. For such a purpose, the development of multilingual resources of controlled vocabulary is essential. As an example, the Dewey Decimal Classification has been expanded into the Universal Decimal Classification system, available in three languages (French, English, and Standard German (German)) and with increased flexibility through thesaural relations. Much more effort is needed in multilingual resource development for use in automatic indexing and other applications.

Back-of-the-Book Indexing

With collections (and the Web) containing not only more but also longer documents, interest in multidocument indexing and abstracting as well as in intradocument indexing and browsing is emerging. Identifying sections of documents with different index terms somewhat takes us back to back-of-the-book indexing, well known by human indexers but barely discovered by the natural language community. Nevertheless, important related activities, such as keyphrase extraction and term extraction, have been explored. Like back-of-the-book indexing, these activities are concerned with the extracted terms themselves as representative of the content of the text and not with their role in information retrieval. Keyphrase extraction focuses on single documents generating a small index list for use as a condensed abstract of a document. Term extraction focuses on multidocuments generating a large index list for full coverage of a domain with interrelations between terms. A KWIC tool can easily link the extracted terms (or keyphrases) to their context of occurrence in a document. Much less obvious is how to find not all but significant contexts and passages related to a term. This feature is unique to back-of-the-book indexing and important efforts should be applied in this area for future research on indexing.

Keyphrase Extraction

The intent of keyphrase extraction is to serve a highly condensed summary of a text to a human reader in the form of a short list of keyphrases. These keyphrases can be seen as highly selective index terms. They can be highlighted in the text for facilitating reading (skimming).

Jones and Paynter (2002) surveyed three keyphrase extraction systems, two of which investigate machine learning approaches, using texts containing author-assigned keyphrases to train their model. Although keyphrase extraction uses features similar to those used in natural language indexing (term frequency, inverse document frequency, and position in document), viewing the extraction task as a learning task is unique. It unfortunately has the disadvantage, like any learning task, of requiring labeled data, meaning in this case a collection of documents with author-assigned keyphrases.

Keyphrase evaluation has been attempted in an intrinsic manner (in contrast to the natural language indexing tradition) by looking at the overlap with author's keyphrases. Since many authors' keyphrases are not taken from the text, this type of evaluation is problematic. Human evaluation has also been suggested for a subjective evaluation of how good each keyphrase is. This is very time-consuming and the interjudge agreement is low (see Jones and Paynter (2002).

Term Extraction

Starting with a collection of texts on a single domain, term extraction and organization aim at building a terminological database in which terms are interrelated via semantic relations such as synonymy, hyperonymy, and meronymy. Interestingly, these are also relations found between the headings and subheadings of back-of-the-book index entries.

Most term extraction systems combine statistical and linguistic approaches used in natural language indexing. Savary and Jacquemin (2003) provided a survey and comparative analysis of term extraction approaches. Language-dependent syntagmatic patterns indicative of candidate terms are often used. Such patterns for English could be AN, ANN, AANPN, NN, NPAN, NPN, NPNN, where A is adjective, N is noun, and P is preposition. One main aspect of a construction of a terminological database is that the terms extracted must have term quality. Within the field of terminology, a term shows particular characteristics distinguishing it from other single and multiword units. Most importantly, a term must display a particular meaning within a particular domain. This aspect is also valid for determining whether or not a unit should become an entry in a back-of-the-book index.

Importance is given to discovering term variants and including them in the terminological database. This is essential if such a resource is to be used for normalization purposes as mentioned above. Variants can be of different types. Given a normalized term such as '*genetic disease*,' an inflectional variant can be *genetic diseases*; a syntactic variant, *disease is genetic*; a semantic variant, *hereditary disease*; and a morphological variant, *genetically determined forms of disease* (Jacquemin, 2001).

Any list of terms automatically extracted is examined by a terminologist before being included in a terminological database. Such a process is tedious, and the more effort that is put into limiting the list to appropriate candidates, the more time is saved by the terminologist. Term extraction software offers similarity to machine-aided indexing software, mentioned below.

Not surprisingly, the evaluation of term extraction, performed intrinsically, is time-consuming and subjective. Evaluation is reported as silences (as opposed to recall in information retrieval) and noise (as opposed to precision). To estimate silences, a terminologist must go through a whole corpus to identify terms that should have been included in the terminological database. Given the human effort involved, this is rarely seen. More often, noise is reported when looking for automatically extracted terms that have been judged by terminologists as not qualifying as terms.

Automatic Indexing: The Next Steps

The large body of literature focusing on automatic indexing and its application in information retrieval emphasizes the importance of that tie. Automatic indexing also continues to be seen as two different activities, one of free-term indexing and one of assignment indexing, first reserved for a human indexer and now an integral part of text classification and filtering systems. Both types of indexing have their advantages and disadvantages. Free-term indexing carries ambiguity through synonyms and homographs becoming index terms, but it allows a high degree of expressiveness and flexibility. In contrast, assignment indexing has a controlled way of dealing with synonyms and homographs and does not contain ambiguity but its expressiveness and flexibility are limited (Harter, 1986).

Adaptability should be a major concern when developing new approaches. For example, the reliance on external resources, such as a cataloguing system, can make it difficult to adapt to new texts, as classification codes are fixed and preestablished. Not relying on any external resource assumes that we either attempt automatic or semiautomatic construction of some normalizing resource or opt for a natural language indexing approach. The former solution stills presents a concern about adaptability as automatic thesaurus construction (and latent semantic analysis) usually assumes a fixed collection. The latter solution leads to the difficult paraphrase problem and orients research towards document clustering and iterative indexing via relevance feedback.

With growing interest in automatic indexing, some researchers have wondered about the role left for the human indexer. In addition to providing much insight into human (also called intellectual) indexing, Anderson and Pérez-Carballo (2001a, 2001b) suggested that viewing all documents as being of equal value is adequate and proposed some ideas for the evaluation of the value of a document (user rating, citations, etc). A more important document might then be worth investing human indexer time to make sure as many user searches as possible can lead to it. This is an interesting combination of automatic and human indexing processes. Another type of combination is machine-aided indexing (MAI). As manual intellectual indexing is time-consuming, expensive, and subjective, MAI can help indexers be more consistent within their indexing process (intraindexer) and among a group (interindexer).

In the future, a user's interaction with his or her personal and public environment (the Web) must be better understood by the research community on automatic indexing.

The Web forces a multimedia and multilingual view of documents. For the multimedia aspect, although we did not discuss sound, image, and video indexing in this article, we acknowledge the interest and challenges awaiting those in that field. For example, within broadcasting agencies, it would

be a great advantage to have good indexing of video at the scene level. If closed captions are provided, then text-based indexing approaches can be used on video segments (presegmented by scene, for example). Speech transcripts (generated either automatically via speech recognition or manually) can also lead to text-based indexing. As for the multilingual aspect, it forces us to reconsider some of the English-oriented approaches exposed in this article. Although indexing is not a language-specific activity, some issues might be different in different languages. For example, although finding words can be problematic in English, it is even more so for Asian languages, such as Mandarin Chinese (Mandarin), that have no obvious word boundaries. In such case, *n*-grams (combinations of *n* successive characters) can be an alternative way of indexing. *N*-grams are language independent and have also been used on English texts. Another example is stemming, which would be a more crucial step for highly inflectional languages, such as romanance languages, than it is for English.

As for the user's personal space, the future also lies in better organization of personal and business information. Personal computers now hold gigabytes of text files (as well as e-mails, software products, and images) that are left to the user to organize in a primitive file directory hierarchy, and unless special search programs are used, personal computers are still assumed to be searched by address (file name) and not by content (index terms). There is clearly a mismatch between the efforts used for indexing for the Web and large document collections and those used for personal data management. An equally pressing need is the organization of corporate intranets, which are becoming quite large and which deserve attention to their indexing and normalization processes. Documents, e-mails, and mostly software legacy in companies desperately need proper indexing for better storage and retrieval.

Many long documents are part of personal space, Intranet, and the Web and deserve segment coverage, stimulating more research to be carried out in the field of automatic back-of-the-book indexing for efficient document browsing.

India: Language Situation

E Annamalai, Max Planck Institute of Evolutionary Anthropology, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

Linguistic diversity has been the historical memory of India since even before it became a modern nation after independence. It remains the foundation of its cultural and political edifice in the present. The 114 *languages* enumerated in the 1991 census are an abstraction of 1576 *mother tongues* named by speakers by classifying them under names identified as distinct languages by the census, most of which are major languages. Each of these mother tongues is reported by 10 000 and more speakers, and any mother tongue reported by a lesser number of speakers is not counted in the total. The number of languages is reduced in another way by the decision to keep out of count the mother tongues that are not assigned to any language or language family; some of these unassigned mother tongues are likely to be distinct languages. The number of such mother tongues, which are not assigned to a language or have under 10 000 speakers, is 1796. The mother tongues with less than 10 000 speakers, whether assigned to a language or not, are not listed individually by name; they are clubbed under the name 'other mother tongues' under languages to which they are assigned or under no language when not assigned. The census distinction between mother tongue and language and its way of assigning mother tongues to languages explain partially the decennial difference in the number of languages. For a comparison of the total number of languages: the number enumerated in the census in 1961 was 193, in 1971 it was 105, and in 1981 it was 109 (Bhattacharya, 2002). The linguists differ in their estimate of the number of languages from the census. The number of Dravidian languages, for example, is 17 in the census (1991) and 26 for linguists (Krishnamurti, 2003), who nevertheless differ among themselves in according language status to dialects and so in the number of languages. The Survey of People of India (Singh and Manoharan, 1993), which does not differentiate between mother tongue and language and is based on self-report by ethnic communities (not individuals), puts the number at 191. The preceding shows that the number of languages is an administrative or a linguistic construct. The number of grammatically distinct languages in India can be placed around 200. Given the large population size (1028 million in 2001), language density (the ratio of languages to the population) is low, viz., 1:5 million.

The speaker strength of languages varies from under 30 (Andamanese) to over 337 million (Hindi). Hindi has the largest number (48) of mother tongues (excluding those having less than 10 000 speakers) grouped under it, 19 of which have more than one million speakers. With similar grouping of mother tongues under their name, the speakers of the languages listed in the constitution constitute 96.2% of the population in 1991, which was 95.58, 95.37, and 87.13%, respectively, in 1981, 1971, and 1961. The new additions to the list or schedule in the Constitution alone do not account this decennial increase. As the language is a construct, so too is its speaker strength.

The languages are categorized by their legal status. Twenty-two languages (14 in 1950) are called *scheduled languages* by virtue of being listed in the Constitution for the specified purpose contributing to the development of Hindi as the official language of the country; the place in the list has, however, come to be interpreted politically as constitutional recognition and as representing the nation. No language is given legally the status of the *national language* in the Constitution. The *tribal languages* (101 in 1961, 89 in 1991) are the mother tongues of communities identified as tribal in the Constitution. The languages that

Linguistic diversity has been the historical memory of India since even before it became a modern nation after independence. It remains the foundation of its cultural and political edifice in the present. The 114 *languages* enumerated in the 1991 census are an abstraction of 1576 *mother tongues* named by speakers by classifying them under names identified as distinct languages by the census, most of which are major languages. Each of these mother tongues is reported by 10 000 and more speakers, and any mother tongue reported by a lesser number of speakers is not counted in the total. The number of languages is reduced in another way by the decision to keep out of count the mother tongues that are not assigned to any language or language family; some of these unassigned mother tongues are likely to be distinct languages. The number of such mother tongues, which are not assigned to a language or have under 10 000 speakers, is 1796. The mother tongues with less than 10 000 speakers, whether assigned to a language or not, are not listed individually by name; they are clubbed under the name 'other mother tongues' under languages to which they are assigned or under no language when not assigned. The census distinction between mother tongue and language and its way of assigning mother tongues to languages explain partially the decennial difference in the number of languages. For a comparison of the total number of languages: the number enumerated in the census in 1961 was 193, in 1971 it was 105, and in 1981 it was 109 (Bhattacharya, 2002). The linguists differ in their estimate of the number of languages from the census. The number of Dravidian languages, for example, is 17 in the census (1991) and 26 for linguists (Krishnamurti, 2003), who nevertheless differ among themselves in according language status to dialects and so in the number of languages. The Survey of People of India (Singh and Manoharan, 1993), which does not differentiate between mother tongue and language and is based on self-report by ethnic communities (not individuals), puts the number at 191. The preceding shows that the number of languages is an administrative or a linguistic construct. The number of grammatically distinct languages in India can be placed around 200. Given the large population size (1028 million in 2001), language density (the ratio of languages to the population) is low, viz., 1:5 million.

The speaker strength of languages varies from under 30 (Andamanese) to over 337 million (Hindi). Hindi has the largest number (48) of mother tongues (excluding those having less than 10 000 speakers) grouped under it, 19 of which have more than one million speakers. With similar grouping of mother tongues under their name, the speakers of the languages listed in the constitution constitute 96.2% of the population in 1991, which was 95.58, 95.37, and 87.13%, respectively, in 1981, 1971, and 1961. The new additions to the list or schedule in the Constitution alone do not account this decennial increase. As the language is a construct, so too is its speaker strength.

The languages are categorized by their legal status. Twenty-two languages (14 in 1950) are called *scheduled languages* by virtue of being listed in the Constitution for the specified purpose contributing to the development of Hindi as the official language of the country; the place in the list has, however, come to be interpreted politically as constitutional recognition and as representing the nation. No language is given legally the status of the *national language* in the Constitution. The *tribal languages* (101 in 1961, 89 in 1991) are the mother tongues of communities identified as tribal in the Constitution. The languages that

Table 1 Scheduled languages and their mother tongue speakers (1991)

Language	*Speakers*	*Percentage*

*Indicates the language included in the eighth schedule through a constitutional amendment and the number of stars indicates the three occasions when the amendment was enacted since the Constitution was adopted in 1950.

are not listed in the Constitution or are not spoken by tribes are commonly called *nonscheduled and nontribal languages*. They are five in 1991. The *official languages* in the states and the Union, which could be from any of these three categories, are 18, which are voted by legislatures to be the languages of governance. The *regional languages* are those that have a literary tradition and belong to an identifiable region of the country. The division of the country into states based on the majority language makes the regional languages generally, not necessarily, the official languages of the states. English, which is neither a scheduled, tribal, or regional language, is a coofficial language of the Union and the official language of one state (Nagaland); it is continued to be used in administration in practice in most states as the legacy continued from the colonial past. The Central Literary Academy lists 22 *literary languages* (not coterminous with the scheduled languages) to be eligible for national literary awards.

The languages in these categories are not mutually exclusive, and they crisscross. A scheduled language (Sanskrit, Sindhi, Nepalese [Nepli], Maithili, Bodo, Santali), for example, may not be an official language of a state. An official language (Mizo, Khasi) may not be scheduled and may be tribal. Two tribal (Bodo, Santali) and one mother tongue subsumed under Hindi (Maithili) are scheduled languages. This reflects the historical and political characteristics of language status in the multilingualism of India (Table 1).

Table 2 Language families and their speakers (1991 census)

	Number of languages	*Percentage of population*
Indo-European	20	75.30
Dravidian	17	22.53
Austro-Asiatic	14	1.13
Sino-Tibetan	63	.97

Ethnic and linguistic communities are not coterminous. Although there are 4635 ethnic communities in India according to the Survey of People of India (Singh and Manoharan, 2003), its contemporary census report (1991) gives a total of 3372 mother tongues, irrespective of their population size. This suggests that language is not the sole identification of ethnicity, and ethnically different communities have the same mother tongue. This also suggests language shift mostly from the mother tongue of a minor community to the mother tongue of a major community. Fifty-eight per cent of speakers from tribal communities had a nontribal mother tongue in 1981, which is an increase from 51% in 1971 and 43% in 1961. Though no figures are available of mother-tongue shift of an entire tribal community, the individual shifts suggest possible existence of community-wide shifts. The preceding figures show that though India is traditionally a country with stable multilingualism among minorities, language shift is on a gradual increase, particularly in tribal communities integrated into the market economy controlled by the majority communities.

Historically, the languages of India belong to four large genetic families leaving out the unclassifiable languages (mother tongues). They are Indo-European (Indo-Aryan and Dardic), Dravidian, Austro-Asiatic (Munda and Mon-Khmer) and Sino-Tibetan (Tibeto-Burman and Thai). The largest number of languages is Tibeto-Burman followed by Indo-Aryan, Dravidian, and Munda. All the languages of Sino-Tibetan (except Meithei) and Austro-Asiatic are tribal. Languages whose literary traditions started before the colonial period are 11 in Indo-Aryan, one in Dardic (Kashmiri), four in Dravidian, and one in Tibeto-Burman (Meithei). Indian languages use 10 script systems other than a revived old script (for Meithei) and a newly invented script (Ol chiki for Santali); eight of the major scripts are derived from Brahmi, of which Devanagari is used by more numbers of languages; two (Perso-Arabic and Roman) are exocentric (Table 2).

Figure 1 Distribution of languages. Figures in brackets refer to the number of languages (inclusive of mother tongues grouped under them) in each language-family. Reproduced from www.ciil.arg, based on the 1991 Census, Central Institute of Indian Languages, with permission.

The geographic distribution of languages does not match their genetic affiliation except that the Sino-Tibetan languages are endemic to the northeastern region, and Munda languages are concentrated in the hilly tracts of the eastern-central region (see **Figure 1**).

The demographic distribution of languages is such that there is no majority language at the national level. The speakers of Hindi, including all mother tongues under it, constitute less than 50% of the total population, and its mother tongue speakers are regionally concentrated. At the state level, however, there are majority languages with their demographic strength ranging from 96% (Kerala) to 63% (Manipur); there are also states like Nagaland and Arunachal Pradesh with no majority language. Each of the 28 states from the smallest to the largest is multilingual like the country. This multilingualism is recognized by the language policies at the state level to a greater extent in education and to a smaller extent in public administration, judicial processes, and business transactions. At the national level, multilingualism is more widely distributed with the use of the majority language of the states not only in the domain of education but also in other domains.

There are 18 official languages in India including the two (Hindi and English) of the Union government. This number increases when the languages that are given official status in a specific region within a state are included. Thirty-three languages are offered as medium of school education, and 41 languages are offered for teaching (NCERT, 1999). The students learn three languages (at least two in one state (Tamilnadu) and in schools run by the central government), which are the official language of the state and the two official languages of the Union. The students of states where Hindi is the official language learn

another Indian language; the students of linguistic minorities, which has the demographic strength to influence educational policy, can learn their mother tongue in lieu of one of the three school languages at some level of school education or in addition to them.

Despite their different genetic origins, the languages of India have converged to share grammatical features due to intensive and extensive interaction between their speakers, which makes India a linguistic area. Coupled with shared cultural beliefs and practices, the linguistic convergence facilitates communication across linguistic regions. India is a communication area, where multilingualism is not a barrier to communication. Indian multilingualism is not just demographic with 200 languages, and it is functional with scores of languages being used in public domains like public administration, education, and judiciary, as indicated earlier. There are languages restricted to private domains supporting family life (including endogamous marriage) and cultural practices (including religious rituals). They are minor and minority languages, which may be endemic to a place or transplanted from another place. Although their use in private domains helps their maintenance over generations, they make multilingualism pyramidal. There are more languages used in private domains than in public domains. There are more languages used in lower levels in public domains than in higher domains. The functional hierarchy and stratified status of languages based on their history, demographic strength, and political power lead to language conflicts. The conflicts range from claiming recognition for public function and legal status, to claiming territory to bring the speakers of a language under one political jurisdiction or to be in majority to have political and administrative control to promoting one variety of a language as the standard for upward mobility over others (Annamalai, 1979). The language conflicts are resolved by conceding to, or compromising on, the demands. The switch from the constitutionally mandated one official language of the Union (Hindi) to two languages (Hindi and English), extension of the constitutional list of languages, reorganization of state boundaries along language lines, and addition/deletion of languages taught in schools are some examples of the results of such a political process. The democratic political system of the country makes political solutions to language conflicts possible.

Multilingualism is the expression of the functional relationship between languages, which is shaped by the political, economic, and cultural values the languages have. The values are bound to change due to external factors such as political and economic changes and ethnic and human rights awareness. They have changed for Indian languages since independence. The position of English in Indian multilingualism has changed from being the symbol of colonial power and exploitation to be the symbol of economic and technological power for the progress of the country and the individuals. This change has created divergence between the language policy of the government and language preference of the people. There is increasing market demand for schools in the private sector to teach subjects in schools through the medium of English as a way of learning English. English, which has been the language of the elite, has increased its seductive power to be embraced by the general population. This is a change with significant consequences to Indian multilingualism.

Although the bilingualism in English is believed to give an advantage to Indians to link with the world, there is grassroots bilingualism in Indian languages, mostly in Hindi or a regional language. The link between the common people is through this bilingualism. Communication is smooth because the language boundaries in grassroots bilingualism are porous, enabling people to move easily between languages. Language competence is not aimed at the standard variety of the languages and is contingent on the need to perform the distributive functions specified for the languages. Indian multilingualism is marked by distributed use of languages and relative competence in them.

Ancient Sanskrit Lexicography

The native lexicographical tradition in India goes back to ancient Sanskrit literature. A dictionary is usually called **nighantu** or **kosha** in modern Indian languages. These terms go back to Sanskrit, where the term *nighantu* has no meaning other than a lexicon, but the term *kosha*, like thesaurus, originally meant a store or treasury. The nighantus, which are concerned with the interpretation of sacred literature, are glossaries of obscure words found in Vedic texts. A scholar called Yaska, who lived a couple of centuries before Christ, prepared a work known as **nirukta** 'explanation', which is an etymological commentary on the words found in a nighantu. Therefore, the term *nirukta* has now come to mean 'etymology'. The koshas, which are not based on any specific texts, have some unusual properties. They are written in verse and include nouns and indeclinables but not verbs. The words are arranged according to topics. They deal with synonyms and homonyms and were meant for the use of poets. The best-known kosha in Sanskrit is the lexicon prepared by a Buddhist scholar, Amarasinha, who was also a poet. This dictionary is usually known as *Amarakosha* ('Amara's dictionary') rather than by its actual name, *Namalinganushasana*. Amarasinha is believed to have lived in the sixth century A.D. This native lexicographical tradition prevailed for centuries in Sanskrit, Middle Indo-Aryan, and Modern Indo-Aryan languages.

European Influences

In the 17th century, European scholars studying Indian languages started preparing bilingual dictionaries for Indian languages modeled on European dictionaries. Several of Indian are comprehensive works, which are not limited to the basic vocabulary items of the language and their meanings but truly present a glimpse of the life and culture of the people that speak the language. Because the Portuguese arrived in India earlier than other Europeans, it is not surprising that the earliest European dictionaries of Indian languages were prepared by them. The Portuguese Jesuit Henrique Henriques is said to have prepared a Tamil–Portuguese dictionary prior to 1550, but no copy of that work has been found. Three prominent works among the extant ones are Diogo Ribeiro's *Vocabulario da lingoa canarim,* a Konkani–Portuguese dictionary compiled in Rachol, Goa, in 1626; Antaõ de Proença's *Vocabulario tamulico com a significaçam Portugueza,* published in 1679; and Manoel da Assumpçam's *Vocabulario em idioma Bengala e Portuguez,* published in 1743. Ribeiro's *Vocabulario* was not published. The full title of Ribeiro's work indicates that it is based on the work of earlier Jesuit scholars. Prominent among them was Thomas Stephens, the first Englishman in India, and the author of the first printed grammar of Konkani. Ribeiro's dictionary is closely modeled on the dictionaries of Latin and Greek. It faithfully follows this tradition in citing the various parts of speech: the verbs are cited in the first person singular present. The nouns are cited in the nominative singular followed by the oblique singular suffix. In Greek and Latin dictionaries, the nominative singular is followed by the genitive singular. It should be noted, however, that the Konkani oblique, having evolved from an earlier genitive, often indicates the genitive case without further marking. The adjectives are cited in the nominative singular masculine, followed by the nominative singular feminine and the nominative singular neuter suffixes. Ribeiro's dictionary has copious information on the religious beliefs, rituals, customs, and etiquette of the Goan people.

The Jesuits in Goa devised a systematic Roman transcription for Konkani, which was used in Ribeiro's Konkani dictionary as well as other Konkani works produced by them. We can appreciate its significance when we compare these works with the early Hindi works prepared in the 18th century, such as Captain George Hadley's *Grammatical remarks on the practical and vulgar dialect of the Indostan language, commonly called Moors, with a vocabulary, English and Moors* (published in 1772), where the representation of Hindi sounds in Roman transcription is chaotic. Soon after, however, Sir Willam Jones devised a systematic Roman transcription that could be used for Sanskrit and modern Indian languages. He was, of course, unaware of the transcription devised by the Jesuits in Goa about 200 years earlier. A Roman transcription based on the transcription of Sir William Jones, often in addition to the native script, has been adopted in many dictionaries of Indian languages published in the 19th and 20th centuries.

Several noteworthy bilingual dictionaries of Indian languages prepared by European scholars appeared in the 19th century. William Carey, who had already published a Marathi–English dictionary in 1810, published *Dictionary of the Bengalee language* in 1825. Carey was a Baptist missionary whose primary mission was the translation of the Bible. He is known for his study of several Indian languages

such as Bengali, Oriya, Panjabi, Marathi, Telugu, and Kannada. James Molesworth is known for his Marathi–English dictionary (*A dictionary of Marathi and English,* 1831, 2nd edn. 1857) and English–Marathi dictionary (*A dictionary, English and Marathi,* 1847, 2nd edn. 1873). When he was about 16 years old, Molesworth joined the army and came to India. He acquired great proficiency in languages like Marathi and Hindi and was given an appointment as a linguist in the Native Infantry. Monier Monier-Williams' English–Sanskrit Dictionary (*A dictionary, English and Sanskrit*) appeared in 1851 and *Sanskrit–Eng Dictionary* in 1872 (2nd edn. 1899). Monier-Williams was Boden Professor of Sanskrit at Oxford University. The monumental *Sanskrit Wörterbuch* (a Sanskrit–German dictionary, also known as the Petersburg Dictionary), compiled by Otto Böhtlingk and Rudolph Roth, appeared during the period 1855–75. *A dictionary, Telugu and English* by Charles P. Brown was published in 1852. He was also the author of many other learned works. *A dictionary in Assamese and English* by M. Bronson appeared in 1867. *A dictionary of Urdu, classical Hindi, and English* by John Platts, who taught Persian at Oxford University, appeared in 1884. Although it is not called a dictionary, William D. Whitney's *The roots, verb forms and primary derivatives of the Sanskrit language* (1885) presents the Sanskrit verb roots arranged alphabetically along with their derived forms. In the last decades of the 19th century, German missionaries from the Basel Mission published dictionaries for coastal Dravidian languages such as Kannada, Malayalam, and Tulu through the Basel Mission Book and Tract Depository, Mangalore. Among these works, Gundert's *A Malayalam and English dictionary* appeared in 1872. The best-known work among the Basel Mission publications is Ferdinand Kittel's *A Kannada–English dictionary,* published in 1894. Kittel's dictionary has an abundance of Kannada idioms and sayings. It includes both Old Kannada and Modern Kannada vocabulary. Although statues of other Europeans have been brought down in India after the country became independent, a statue of Ferdinand Kittel was installed in Bangalore (the capital of the Kannada state, Karnataka) in 2001 in recognition of Kittel's lexicographical contribution. It was inaugurated by the chief minister of the state.

Although an English dictionary, Yule and Burnell's *Hobson–Jobson,* published in 1886, deserves to be mentioned in an article on the dictionaries of Indian languages, because it deals with the history of thousands of words of Indian origin that were used by the British in India.

More bilingual dictionaries that are equally noteworthy were published in the 20th century. George Grierson's *A dictionary of the Kashmiri language* was published in 1916–32. *The Pali Text Society's Pali–English dictionary* by T. W. Rhys Davids and William Stede appeared in 1921–25. *Tamil lexicon,* edited by J. S. Chandler, S. V. Pillai, and others, appeared 1924–38. Ralph Turner's *A comparative and etymological dictionary of the Nepali language* appeared in 1931. P. O. Bodding's *A Santal dictionary* appeared in 1934.

Turner's *A comparative dictionary of Indo-Aryan languages* (1966–71) and *A Dravidian etymological dictionary* by Thomas Burrow and Murray Emeneau (1968, 2nd edn. 1984) have made a significant contribution to the study of comparative Indo-Aryan and Dravidian linguistics. A project for the preparation of a comparative Indo-Aryan dictionary was envisaged by Turner in the early decades of the 20th century. It was proposed by Sir George Grierson that such a dictionary should form an appendix to the volumes of his great linguistic survey of India in 1920. Turner lived long enough to publish his splendid work almost 50 years later. Manfred Mayrhofer's *Kurzgefasstes etymologisches Wörterbuch des altindischen,* published in 1956–80, is a valuable contribution to Sanskrit etymological studies.

The Rise of Indigenous Lexicographic Scholarship

Many noteworthy dictionaries, monolingual as well as bilingual, were published by Indian lexicographers toward the end of the 19th century and in the 20th century. Among the major monolingual dictionaries of Indian languages that appeared during this period, one can mention Kashi Nagari Pracharini Sabha's *Hindi shabdsagar* (a Hindi dictionary), edited by Shyamsundardas and other Hindi scholars (1929), *Maharashtra shabdkosh,* edited by Date and other Marathi scholars (1932–38), *Rajasthani sabadkos,* by Sitaram Lalas (1962), and *Kannada nighantu,* by G. Venkatasubbiah (1971–79).

V. S. Apte's *The practical Sanskrit–English dictionary* appeared in 1890. Its substantially revised and enlarged version by P. K. Gode and C. G. Karve was published in 1957. Hargovind Das's *Paia Sadda Mahannavo* (a Prakrit–Hindi dictionary) appeared in 1923. The *Ardhamagadhi dictionary* by Shatavadhani Jain Muni Shri Ratnachandraji Maharaj also appeared in 1923. The second edition of Hardev Bahri's *English–Hindi dictionary* appeared in 1969. Sukumar Sen's *An etymological dictionary of Bengali (1000–1800 A.D.)* was published in 1971.

Monsignor Sebastião Dalgado, a Goan priest and lexicographer, who prepared a Portuguese–Konkani dictionary in 1883, a Konkani–Portuguese dictionary in 1893, and *Influência do vocabulário Português em línguas Asiáticas* in 1913 (translated into English by A. X. Soares in 1936 under the title *Portuguese vocables in Asiatic languages*), published his magnum opus, *Glossário Luso-Asiático*, in 1918–21. This work, which is modeled after Yule and Burnell's *Hobson–Jobson*, deals with lexical items from Indian languages as well as other Asiatic languages that have entered the Portuguese language.

Several dictionaries dealing with special vocabularies have appeared in the last few decades. Krishnamurthi's *Mandalika vrittipadakosam*, which appeared in 1962, is a Telugu dictionary of agricultural vocabulary. Helmut Nespital's *Dictionary of Hindi verbs* appeared in 1997. Several such dictionaries, such as *Rajpal English–Hindi dictionary of technical terms* by Hardev Bahri (4th edn., 2001), are concerned with technical terminology.

A number of major works on Indian languages by Indian or foreign scholars have appeared since 1980. Panjab University's *English–Punjabi dictionary* appeared in 1981. In 1984, Central Hindi Directorate (which is under the Ministry of Human Resources Development, Government of India) published *Bharatiya bhasha kosh* (a dictionary of Indian languages), which is a 14-language dictionary: Hindi to Panjabi, Urdu, Kashmiri, Sindhi, Marathi, Gujarati, Bengali, Assamese, Oriya, Telugu, Tamil, Malayalam, and Kannada. Central Hindi Directorate has also published several trilingual dictionaries (regional language–Hindi–English or Hindi–regional language–English) such as *Gujarati–Hindi–English trilingual dictionary* (1984–85), *Hindi–Sindhi–English trilingual dictionary* (1989), and *Hindi–Assamese–English trilingual dictionary* (1989). *Tulu lexicon*, a Tulu–Kannada–English dictionary that appeared in 1988–1997, was prepared by U. P. Upadhyaya and his associates after a systematic dialect survey of the Tulu-speaking areas. Both regional dialects and dialects spoken in various communities were investigated. They collected idioms, sayings, and vocabulary from written sources as well as that used in various occupations, at fairs and festivals, in religious ceremonies, folk performances, and games. *The Oxford Hindi–English dictionary* by R. S. McGregor, which appeared in 1993, has fulfilled the long-felt need for a reliable Hindi–English dictionary. The fascicles of Manfred Mayrhofer's *Etymologisches wörterbuch des Altindischen* (an etymological dictionary of Sanskrit), which is an extended version of his *Kurzgefasstes etymologisches Wörterbuch*, started appearing in 1986. A greatly revised version of an English–Kannada dictionary first published by Mysore University in 1946 started appearing in 1989 (second edition, 2000) under the title *The Mysore University English–Kannada dictionary*. The fourth and final volume of this work appeared in 2004.

Individual Recognition in Animal Species

M A Bee, Carl von Ossietzky University, Oldenburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

No empirical evidence is required to convince even the most skeptical reader that humans use distinctive facial and vocal features as cues for recognizing other individuals, and that individual recognition provides the foundation for our social relationships. Based on our own experiences, we also know that the recognition of a particular individual, say a friend or colleague, entails a multifaceted representation, or concept, of that individual. In other words, we often possess knowledge about recognized individuals gained through previous social interactions that goes far beyond the mere characteristic appearances of their faces or sounds of their voices. This knowledge, in part, determines the conditions for our present and future social interactions.

But what can be said of the role of individual recognition in the social behavior of nonhuman animals? There is ample evidence from a range of species that other animals also base many of their social interactions on an ability to recognize other individuals, such as relatives, mates, and members of their social group. However, providing a general and concise answer to questions about 'social recognition' in animals is exceedingly difficult, given the diversity of social recognition systems found in nature, the diversity of species and behavioral contexts in which social recognition has been investigated, and the diversity of approaches and perspectives taken by animal behaviorists in their investigations of social recognition. Therefore, no short review of the subject, including this one, can be comprehensive.

In this article, the basic components common to all social recognition systems, and two general mechanisms that mediate social recognition in animals, are described, and several different perspectives on social recognition in animals are briefly discussed. Because most animal studies investigate the role of communication in social recognition, the article will focus on communication-based social recognition systems. Several evolutionarily important behavioral contexts of communication-based social recognition are described, with an emphasis on acoustically mediated social recognition systems, and three experimental approaches to the study of social recognition in animals are briefly discussed. Finally, a general model of communication-based social recognition is outlined, making explicit how different perspectives on social recognition may be integrated. Readers of this article, especially those not accustomed to thinking about the behavior of nonhuman animals, should keep the following two points in mind:

1. We should expect social recognition systems to differ among species, and these differences should reflect adaptations to different species-typical social environments within constraints imposed by an animal's perceptual and cognitive systems.
2. What humans experience as individual recognition likely represents one end of a continuum of complexity in the evolved perceptual and cognitive abilities that underlie social recognition.

Components and Mechanisms of Social Recognition

Here, 'social recognition' will refer to the ability of animals to recognize different **social categories** of individuals within their own species. The nature of these social categories is always an empirical question. They may be very broad—for example, related versus unrelated individuals, or familiar versus unfamiliar individuals—or each social category may correspond to a particular individual, so that multiple, familiar individuals are recognized as distinct social categories, as is the case for humans.

Social recognition systems have five necessary components:

1. Animals must provide information about their membership in a social category using so-called 'signature signals' or other recognition cues that differ between the social categories that pose the recognition problem;
2. Animals must perceive differences in the signature signals and recognition cues that identify particular social categories;
3. Animals must compare a perceived signal or cue to an internal neural representation that may be either innate or learned;
4. Animals must decide whether a perceived signal or cue matches their internal neural representation; and
5. Animals must posses a behavioral repertoire diverse enough to allow different behavioral responses to different social categories.

These components are explained in further detail later in this article, in the context of communication-based social recognition systems. Readers are referred to Beecher (1990; 1991), Sherman *et al.* (1997), and Bradbury and Vehrencamp (1998) for well-developed and thoughtful treatments of the components of recognition systems.

Animal behaviorists have identified several potential mechanisms that can mediate social recognition. The two mechanisms that have been the subject of most empirical and theoretical studies are 'phenotype matching' and 'familiarity.' An animal's phenotype refers to its observable appearance, characteristics, and behaviors, and it is influenced by the genes it inherits from its parents and by its environment. Phenotype matching occurs when animals match another animal's phenotype to an innate or learned representation of either their own phenotype ('self-referent phenotype matching') or that of a familiar individual. Because the relatedness of two individuals is proportional to the number of copies of genes that they share, and the degree of similarity in their phenotypes is influenced by the number of shared genes, phenotype matching can be one way that animals behaviorally discriminate between relatives and non-relatives, or among animals related by different degrees. In some cases, related individuals, such as siblings, may also live in a common environment that can influence their phenotypes in similar ways, for example, by giving rise to similar odors. Such cues can also mediate social recognition based on phenotype matching, and this represents one form of social recognition that is not based on communication signals.

Social recognition may also be based on mechanisms that involve an acquired familiarity with the phenotypic characteristics that distinguish among social categories. In other words, instead of matching an individual's phenotype to their own or that of another individual, animals learn about and remember the phenotypes of the individuals comprising social categories through prior observations of, or interactions with, those individuals. In this case, recognition is mediated by comparing sensory input with a previously learned representation of the phenotype that identifies the social category posing the recognition problem. Much of the work on the role of familiarity in social recognition has focused on the ability of animals to learn to recognize social categories based on differences in communication signals, and this will be the topic of the remainder of this article. Before describing communication-based social recognition systems in more detail, however, it is worthwhile to first consider a number of perspectives on social recognition in nonhuman animals.

Perspectives on Social Recognition in Animals

Among animal behaviorists, there are different perspectives on the question of social recognition in animals that stem as much from the diversity of social recognition systems as from the rich diversity of approaches used to study animal behavior. One of these perspectives is based in ethology, the biological study of behavior that developed in the first half of the 20th century and attempts to answer questions about the causal mechanisms, development, evolution, and function of animal behaviors. It is from an ethological perspective that social recognition is most often treated as a communication problem. Researchers working from this perspective often define social recognition operationally, in terms of the behavioral discriminations that animals make among social categories and the features of communication signals or other recognition cues that make discrimination possible. Thus, an ethological perspective tends to emphasize the sensory input that makes recognition possible and the behavioral interactions that result from recognition.

The field of behavioral ecology developed as an outgrowth of ethology in the 1970s and focuses on the adaptive value of social behaviors, the ecological and social factors that influence these behaviors, and the mechanisms that allow these behaviors to evolve. Behavioral ecological perspectives on social recognition are more often concerned with recognition as an evolutionary adaptation for directing appropriate social behaviors toward other members of an animal's social group and the implications of recognition for survival and reproduction. Behavioral ecologists also address questions related to the genetic mechanisms that underlie the evolution of social recognition and the ecological and social factors that favor the evolution of social recognition systems.

Following the cognitive revolution that occurred in psychology in the 1950s and 1960s, many of the principles of cognitive psychology, which emphasize internal mental processes, began making important contributions to the study of behaviors in a diversity of animal species in the 1980s and 1990s. This culminated in approaches to animal behavior variously termed 'animal cognition,' 'cognitive ecology,' and 'cognitive ethology.' From a cognitive perspective, social recognition is often treated as a question about social knowledge and social categorization and is defined representationally, in terms of the complexity, specificity, and dimensionality of the internal representations of familiar individuals that result from previous experience. Thus, the cognitive perspective tends to emphasize not sensory input and behavioral output, nor the evolution of social recognition, but instead the internal processes and representations that are involved in social recognition and the roles that such representations play in social interactions.

All of these perspectives are valuable because they address different, but related, questions about social

recognition that complement one another. Efforts that integrate these different perspectives will likely continue to shed new light on both the mechanisms and evolution of social recognition systems in animals. As described below, the study of communication-based social recognition systems provides rich opportunities for integrating these perspectives.

Communication-Based Social Recognition Systems

A simple conceptualization of animal communication would consist of an animal acting as a 'sender' to produce a 'signal' that is perceived by another animal acting as a 'receiver.' Communication-based social recognition can be defined operationally as occurring when receivers direct appropriate behaviors toward one or more particular social categories of senders in response to signals, while withholding these behaviors from other social categories of senders, based on an acquired familiarity with distinctive properties of the signals produced by the sender or senders of the social categories to which the behaviors are directed. Several important points about this definition should be made explicit. First, recognition is an inherently internal product of the receiver's nervous system that must be inferred by researchers from the receiver's discriminative behavioral responses to signals produced by senders of different social categories. Second, recognition is based on familiarity with communication signals; that is, learning plays a critical role in allowing receivers to form memories that encode the distinctive properties of signals that distinguish social categories of senders. Finally, the above definition does not require that recognition based on communication signals involve the formation of mnemonic representations that are more complex than representations of signals themselves. However, the possibility that social recognition involves an integrated, multifaceted neural representation of the sender as an external referent is certainly not excluded by focusing on communication-based social recognition.

Defined in this manner, communication-based social recognition has been demonstrated in fish, amphibians (frogs and salamanders), reptiles, birds, and mammals. Moreover, social recognition is mediated by communication signals in a diversity of sensory modalities, including vision, audition, chemoreception, and electroreception, and it occurs in a number of evolutionarily important behavioral contexts. Four behavioral contexts in which communication-based social recognition has been widely studied are kin recognition, territorial neighbor recognition, mate recognition, and so-called 'true individual recognition.'

Behavioral Contexts of Communication-based Social Recognition

Kin Recognition Some animals learn to behaviorally discriminate among related and unrelated individuals, or among individuals related by different degrees, based on differences in communication signals. This form of social recognition, termed 'kin recognition,' is commonly associated either with choosing an optimally related mate, for example to avoid the deleterious effects of inbreeding, or with directing certain behaviors toward relatives that function to increase their survival and reproduction. The study of kin recognition was greatly advanced by the formulation of kin selection theory by behavioral ecologists. Kin selection theory can explain the evolution of some of the apparently altruistic behaviors stemming from kin recognition as adaptations that allow individuals to propagate copies of their own genes into the next generation by improving the survival and reproduction of genetically related individuals.

Kin recognition based on chemical signals called pheromones is well known from rodents and other mammals. Parent-offspring recognition is a form of kin recognition that has evolved numerous times in animals that provide parental care for their offspring, especially in species that have social systems in which the offspring from different sets of parents intermingle while still under the care of their parents. Parent-offspring recognition based on acoustic signals has been studied in colonially breeding species, such as some swallows, seabirds (e.g., penguins), pinnipeds (e.g., seals), and bats. In these colonial species, the young are often left in a communal crèche, sometimes consisting of thousands of densely packed individuals, while the parents leave the area to forage. Parents and offspring are able to reunite in these very crowded social conditions by recognizing individually distinctive vocalizations.

Territorial Neighbor Recognition In species in which individuals defend territories, territory holders commonly exhibit behaviors that indicate that they recognize their nearby territorial neighbors, a form of social recognition termed 'territorial neighbor recognition.' Most commonly, territory holders are shown to exhibit low levels of aggression toward their nearby, established neighbors and high levels of aggression toward unfamiliar 'strangers' that may attempt to take over the territory or to establish a new nearby territory. Displays of lower levels of aggression toward familiar neighbors are thought to evolve in

species that defend long-term multipurpose or breeding territories, as opposed to feeding territories. This form of territorial neighbor recognition is usually presumed to be an evolutionary adaptation that allows territory holders to avoid the costs of repeated aggressive interactions with neighbors that already possess their own territory and therefore represent less of a threat to territory ownership than strangers that may attempt a territory takeover.

Songbirds represent the most thoroughly studied taxon when it comes to neighbor recognition. Territorial male songbirds discriminate among neighbors and strangers, and even among multiple neighbors, based on a combination of individual differences in songs and spatial cues related to the location of a neighbor's territory. Some songbirds even among appear to retain long-term memories of the songs of their neighbors from previous breeding seasons. Similar acoustically mediated recognition systems have also been described in territorial seabirds, fish, and frogs, although long-term memories for neighbors' signals have not been investigated in these taxa. Neighbor recognition has also been investigated in territorial lizards, which can recognize their neighbors based on visual and chemical cues. Some electric fish may also recognize neighbors based on individual differences in self-generated electrical signals known as electric organ discharges.

Mate Recognition Another form of social recognition, termed 'mate recognition,' refers to behavioral discrimination by an individual between its mate or breeding partner and other members of the same species. Mate recognition can play a role in maintaining the pair bond and in synchronizing shared parental duties, such as the care of eggs or young. An ability to recognize one's mate is particularly important in socially monogamous species that form long-term pair bonds. Mate recognition based on acoustic signals has been most studied in animals that live in large colonies, such as colonial seabirds, in which parents coordinate their parental care duties, and in which spatial cues may provide little assistance in locating a mate. Because of other uses of the term 'mate recognition' in the literature, it is important to distinguish this form of social recognition from 'species recognition'; 'mate recognition' is often used to describe the recognition of an individual of the opposite sex as a member of the same species and therefore as a potential mating partner.

'True Individual Recognition' Finally, a number of studies of so-called 'true individual recognition' demonstrate that some animals recognize multiple, familiar, and often unrelated individuals as distinct and unique social categories. This form of social recognition, which bears its somewhat anthropocentric name in part because it approaches more closely our own human experience, appears to function in animal species with highly developed social structures, in which individuals often live in organized social groups. For example, in bottlenose dolphins, in which individuals form long-lasting associations, individual dolphins can discriminate among multiple familiar individuals based on individual differences in so-called 'signature whistles.' Some birds, such as the song sparrows described later in this article, may also be capable of such true individual recognition based on individual differences in vocalizations.

A number of studies of social cognition in nonhuman primates have established that some primates not only recognize multiple familiar individuals as distinct social categories – both visually and acoustically – but they also possess social knowledge about these individuals, such as the social alliances they form, their relatedness to other individuals, and their rank order in dominance hierarchies. This is the case, for example, with group-living baboons, which are discussed in more detail later. Thus, it seems clear that, like humans, some other animals, such as highly social, group-living primates, are able to form integrated, multifaceted representations of multiple familiar individuals that are more complex than a mere representation of communication signals or other simple cues associated with these individuals.

Methods Used to Investigate Communication-Based Social Recognition

Because social recognition is an internal process that involves comparing sensory input to an internal neural representation, and because nonhuman animals cannot simply tell us about their recognition experiences, the study of social recognition in animals requires observations and experiments that inform us about an animal's recognition abilities based on its behavioral interactions with other individuals or its behavioral responses to communication signals from different social categories of senders. Three experimental designs that are commonly used to investigate communication-based social recognition are 'discrimination experiments,' 'habituation-discrimination experiments,' and 'conditioning experiments.'

Discrimination Experiments In a discrimination experiment, typically two different signals are presented to test the hypothesis that the intended receiver will behaviorally discriminate among the signals, at least one of which is presumed to be familiar to the subject. The alternatives might be familiar versus

unfamiliar signals, the signals of two different familiar individuals, or the unmodified signal of a familiar individual versus an experimentally modified version of the same signal. Experiments usually consist of either presentations of different alternatives in separate test periods separated by some intervening time interval, or simultaneous presentations in a two-alternative choice test. Some experiments use actual conspecific individuals as stimuli instead of experimentally presented communication signals.

Habituation-Discrimination Experiments The habituation-discrimination paradigm involves repeatedly presenting a response-eliciting stimulus during an initial 'habituation phase' until the response habituates. The stimulus is often a communication signal from a particular social category, although real individuals are sometimes used. During a subsequent 'discrimination phase,' subjects in the control group experience additional presentations of the habituating signal, and subjects in experimental treatment groups experience novel signals that are in some way different from the habituating signal, such as a signal from a different social category. The prediction is that if subjects perceive the novel stimulus as the signal of a new or different social category, then the habituated responses of the treatment groups should be greater than those of the control group during the discrimination phase.

Conditioning Experiments In conditioning experiments, subjects are trained, using classical or operant conditioning techniques, to respond differently to signals from different social categories of senders. In contrast to discrimination experiments and habituation-discrimination experiments, which take advantage of an animal's natural behavioral repertoire and can therefore be conducted in the field, conditioning experiments are conducted under controlled laboratory settings that involve the experimenter determining what constitutes a correct behavioral response. In classical conditioning experiments, the behavioral response often involves some sort of reflex to a stimulus (e.g., Pavlov's salivating dogs). The responses in operant conditioning experiments often involve behaviors such as pecking a lighted response key or pressing a lever in response to a stimulus to obtain a food reward and to avoid punishment. Once animals are trained to distinguish among social categories with a certain level of correct responses, recognition abilities are then tested in probe trials in which test signals belonging either to the same social categories or to different ones are presented to test the subject's ability to distinguish among social categories.

A Model of Communication-Based Social Recognition

Given the importance of communication in the social recognition systems of animals, including humans, it is worth illustrating a general model of how communication signals can mediate social recognition. One requirement for communication-based social recognition is that communication signals be distinctive among the social categories of senders that pose the social recognition problem. These so-called 'signature signals' can arise when the signals produced by senders of different social categories differ in the presence/absence of certain signal attributes, or as illustrated in Figure 1, when the among-category variation in signals exceeds the variation that occurs within social categories.

The two-dimensional and three-dimensional plots in Figure 1 illustrate two important points. First, signals usually vary in multiple dimensions that can potentially provide independent information about a sender's membership in a particular social category. Second, the signals of different social categories may be well separated along some signal dimensions, while there may be extensive overlap along other signal dimensions. For example, the signals of social categories 4 and 5 in Figure 1 overlap considerably along signal property 2 but are well separated along signal properties 1 and 3. It may be the case that at least some social categories overlap on all signal properties. We should, therefore, expect receivers to evolve to use as recognition cues those signal properties that most reliably distinguish among senders from different social categories.

The comparative work of Beecher and colleagues on vocally mediated parent-offspring recognition in swallows has highlighted the fact that evolution can also act directly on the signals produced by senders, making them more distinctive among social categories in species in which social recognition is evolutionarily advantageous. The calls of chicks in colonial-breeding cliff swallows and banks swallows, in which young are left in communal crèches, and in which parents rely on calls to reunite with their chicks, are more individually distinct than the calls of chicks in the solitary-breeding barn swallows and rough-winged swallows, in which the requirements for parent-offspring recognition are less demanding.

The Basic Model

Figure 2 depicts a multistage hierarchical model of communication-based social recognition that highlights the internal processes of the receiver's nervous system that mediate recognition. While the stages in the model may be expected to vary somewhat

Figure 1 Schematic illustrations of distinctiveness in communication signals among social categories of senders. *Top:* Two probability density functions illustrating the likelihood that two social categories (1 and 2) have the specified values of a single signal property. *Middle:* Scatter plot illustrating the values of 15 signals from each of five social categories (individuals in this case) in a two-dimensional 'signal space.' Each axis represents values for a different signal property. For example, for an acoustic signal, the two signal properties might represent spectral frequency and signal duration. *Bottom:* Scatter plot illustrating the separation among social categories in a three-dimensional signal space bounded by values of three signal properties. Axis values in all three plots represent deviations of signal properties from a standardized population mean value of zero. (Top and middle figures adapted from Insley *et al.,* 2003.)

according to sensory modality, for the most part, similar or parallel processes should be expected across sensory modalities.

Figure 2 Schematic model of communication-based social recognition. The model depicts the processes involved in recognition that take place in the receiver's nervous system. The open arrow *(bottom)* depicts the requirement that senders produce signals that are distinctive among the social categories of senders posing the recognition problem (see **Figure 1**). Thick black arrows depict bottom-up processes leading from sensory transduction of a signal to the behavioral output of the receiver. Dashed arrows depict potential top-down influences of recognition on earlier perceptual processes. Thin black arrows depict possible associations between the mnemonic representation of the signal and other sources of information encoded in memory that can influence the decision rule and recognition, as well as the observed behavioral output. Note that the hierarchical arrangement of stages in the model does not necessarily imply that processing between stages is organized sequentially. (Adapted from McAdams, 1993.)

The perceptual processes involved in communication-based social recognition begin in the receiver's sensory system, with the transduction of communication signals into neural activity. The sensory system may then be required to perform some kind of perceptual grouping, by which the neural representation of the to-be-recognized signal is perceptually segregated from those of other signals, stimuli, or noise in the environment and integrated into a coherent perceptual object based on the signal's physical and temporal properties. Once a perceptual object of a perceived signal has been formed, the sensory system must analyze this representation to determine the perceived signal's salient properties. The properties of a receiver's perceptual representation of the signal must then be compared to those of a mnemonic representation of the signal that was formed as a result of previous

Figure 3 Matching between perceptual and mnemonic representations of signals. Receivers must use some form of a decision rule to determine whether or not their perceptual representation of a signal adequately matches the representation stored in their memory. The shaded area represents the probability that the perceived signals of a sender from the to-be-recognized target social category *(top)*, or a sender from outside the target category *(bottom)*, will be accepted (i.e., recognized) as coming from a sender of the target social category, given the location of the receiver's decision rule (vertical bar). The variance in the receiver's mnemonic and perceptual representations of a sender's signals can arise from sources such as within-individual variation or habitat-induced variation in the sender's signals and internal noise resulting from spontaneous neural activity and the statistical nature of stimulus-driven neural activity in the receiver's nervous system.

recognition learning. At this stage, receivers must use some decision rule, or matching algorithm, to determine whether their perceptual representation of the signal adequately matches their representation in memory, followed by a judgment about the sender's category membership.

The matching process between a receiver's perceptual and mnemonic representations of a sender's signal is sometimes modeled as two probability density functions of the values of some signal property that serves as a recognition cue (Figure 3). The probability distributions on the left in Figure 3 represent the receiver's mnemonic representation, which encodes a range of values for a particular signal property that can be attributed to senders from a particular social category with a specified probability; the distributions to the right represent the receiver's perceptual representations, which encode a range of values for the same signal property after perceiving a signal, again with a specified probability. If there is an adequate match between the perceptual and mnemonic representations, as illustrated in the upper panel of Figure 3, then recognition can be said to occur and the receiver should accept the sender as belonging to a particular target social category (e.g., mate, parent, offspring, or neighbor). The lower panel illustrates a situation in which there is an inadequate match, resulting in the rejection of the sender as belonging to the particular target social category. Evolution should equip receivers with a decision rule that maximizes the number of correct behavioral responses while minimizing the number of recognition errors. Thus the location of the decision rule should depend on the relative benefits of correct responses, the costs of errors, and the probabilities of correct and incorrect responses given the degree of overlap among the signal properties of individuals posing the recognition problem.

Finally, for observers and experimenters to acquire evidence that recognition has occurred, it is necessary that receivers respond differently to signals from different social categories of senders. It is also important to bear in mind, however, that the internal process of recognition may, in fact, occur in the absence of any overt behavioral discrimination if the most evolutionarily appropriate behavior is to respond similarly to different social categories of senders. The fact that recognition can occur in the absence of a behavioral discrimination is a perennial problem in the study of animal recognition systems, especially in the interpretation of negative results.

The Extended Model: Integrating Ethological and Cognitive Perspectives

As stated earlier, we should expect animal recognition systems to differ among species, and these differences should reflect species differences in ecology, phylogenetic history, and the complexity of perceptual, social, and communication systems. A consideration of how species may be expected to differ provides a way to integrate the ethological and cognitive approaches to studying social recognition.

Dimensions of Communication-Based Social Recognition The mnemonic representations of communication signals that are formed through recognition learning and that mediate social recognition (Figures 2 and 3) can be expected to differ among animal species along three dimensions: specificity, complexity, and temporal stability (Figure 4).

'Specificity' refers to the breadth of the social categories that represent the social recognition problem and can range from dichotomous social categories (e.g., related versus unrelated, familiar

Figure 4 Three dimensions of communication-based social recognition. Species should be expected to differ in the specificity, complexity, and temporal stability of their mnemonic representations of recognized communication signals, as well as in the extent that these representations are integrated with other sources of information.

versus unfamiliar, or mate versus non-mate) to the situation where multiple familiar individuals are treated as distinct and separate social categories, such as in so-called 'true individual recognition.'

'Complexity' can refer to at least three different characteristics of a recognition system. First, because multiple properties of communication signals (e.g., spectral and temporal properties of acoustic signals) can exhibit variation that potentially can be used for recognition (Figure 1), complexity can refer to the number of different signal properties encoded in memory within a particular sensory modality. Second, in species that communicate using a repertoire of signals in a particular sensory modality, complexity can refer to the number of signal types that are recognized from a particular social category. Finally, because social recognition in some animals is mediated by multiple sensory modalities, such as vision and audition, complexity can also refer to the number of different sensory modalities involved in recognition.

'Temporal stability' refers to the time over which encoded representations of signals persist in memory. In species in which individuals interact only briefly, relatively short-lived memories may be sufficient to solve any particular recognition problem, whereas in species in which individuals interact over longer periods, or with longer intervals between interactions, long-term memories may be required for social recognition.

Integration of Signals with Other Information Questions related to the extent that mnemonic representations of communication signals are integrated with other sources of information or social knowledge go to the heart of combining ethological and cognitive perspectives on social recognition. Other sources of information may not only facilitate recognition of communication signals but may also have more direct influences on an animal's behavioral response (Figure 2). This information may include memories of previous social interactions, expectations about future social interactions, and previous knowledge about other individuals gained through observations and previous social interactions. The way that representations of acoustic signals can be integrated with other forms of social knowledge is perhaps best illustrated with two examples from the literature.

As mentioned above, an integration of representations of communication signals with social knowledge about recognized individuals is known from primates with complex social structures. For example, Cheney and Seyfarth (1999) used ingenious field playback tests to demonstrate that some species of monkeys, such as baboons, possess information about the family relationships of other individuals. In one experiment, pairs of unrelated female baboons were presented with acoustic playbacks that simulated a fight occurring either between two of their familiar relatives or between two familiar individuals that were not related to either subject. When the acoustically simulated fight, which consisted of previously recorded threat grunts and screams, was presented, females looked toward the speaker longer during the playbacks and looked toward each other longer following playbacks when the simulated fight was between their relatives, as opposed to between two non-kin. Females were also more likely to interact in a friendly manner following a fight between two non-kin compared to a fight between two of their relatives. These results can be interpreted as indicating three important aspects about vocally mediated social recognition in baboons. First, subjects recognized the fighting individuals by their threat grunts and screams, two acoustically different signals. Second, subjects recognized the relatedness between one of the simulated fighters and themselves. Third, subjects recognized the relatedness between the other fighter and the other paired subject. Thus, representations of familiar acoustic signals were integrated with other social knowledge about the senders that included information about relatedness to self and relatedness to others.

The extent to which such integration between representations of signals and social knowledge plays a role in the social recognition systems of

non-primates has unfortunately received much less attention. However, in a study of song sparrows, a songbird in which males recognize their territorial neighbors, the results of playback tests by Beecher *et al.* (1996) suggested that territorial males in this species may also possess social knowledge about their territorial neighbors. In song sparrows, neighboring territorial holders tend to share a number of song types in their song repertoires. When the songs of a familiar neighbor were played back from the neighbor's territory, subjects responded by singing a song type that they shared with that neighbor, but that was different from the song type sung by the simulated neighbor. In contrast, when a stranger's song was presented from a neighbor's territory, subjects responded with a song type from their repertoire that they did not share with that particular neighbor. These results suggest that male song sparrows recognize an individual neighbor as a distinct social category (i.e., 'true individual recognition'), that they possess knowledge about the song types that they do and do not share with their recognized territorial neighbors, and that this social knowledge plays a role in social interactions over territory boundaries.

In addition to social knowledge about other individuals, receivers may also possess information about the significance of current spatial or contextual cues related to the context in which the signal was perceived (Figure 2). Spatial location is often regarded as an important cue in some forms of recognition. For example, what could appear on the surface to be parent-offspring recognition may, in fact, represent behaviors guided by a simple rule followed by a parent, such as 'find the nest and feed the young in the nest.' Therefore, studies of social recognition often strive to demonstrate the location-independence of behaviors thought to be guided by social recognition. In some recognition systems, however, spatial or contextual cues may also function as what psychologists refer to as 'occasion setting stimuli,' in which the recognition of a signal in one context elicits one behavioral response, while recognition of the same signal in a different context elicits a different response. One example of this may be the location-specificity of reduced levels of aggression between territorial neighbors. In songbirds, hearing a neighbor's songs from the direction of the neighbor's territory elicits low levels of aggression, while hearing the same song played back from a different or 'incorrect' location elicits an intense aggressive response. It is usually presumed that a familiar neighbor singing from an unfamiliar location represents a threat to the status quo of established territorial boundaries. Thus, information about context can directly influence a receiver's behavioral response to a recognized signal.

Looking Forward

One challenge for future research is to understand the nature of the neural representations that underlie communication-based social recognition in terms of their specificity, complexity, and temporal stability; the processes that lead to their formation; and the extent to which neural representations of communication signals are associated or integrated with other encoded information and social knowledge about the sender. A second challenge for future comparative research is to discover the ecological and phylogenetic bases of similarities and differences among species in the learned representations involved in social recognition and their underlying neural mechanisms. More effort should be made by animal behaviorists to integrate, both within and across species, an understanding of the internal processes mediating social recognition, such as those illustrated in Figure 2. It will be important in these endeavors to keep in mind that the representations underlying recognition in different animal species likely fall along continua of specificity, complexity, and temporal stability and are likely to differ in the extent to which they are integrated into multifaceted representations of recognized individuals. Therefore, exploration of social recognition in animals will require a genuine willingness to examine recognition systems in terms delimited by the animals' social, perceptual, and communication systems.

Indo-Aryan Languages

Indo-Aryan languages (sometimes also called 'Indic' languages) are spoken in India, Pakistan, Bangladesh, Nepal, Sri Lanka, Bhutan and Maldives – the group of seven countries also known as the South Asian Association of Regional Cooperation (SAARC) countries. More than two-thirds of the total population of South Asia speaks Indo-Aryan languages. Owing to 20th-century migrations, considerable numbers of Indo-Aryan speakers have settled in non-SAARC countries, especially in Europe and North America. Indo-Aryan constitutes the largest language group in the Indo-European language family in terms of numerical weight of speakers (said to be approximately one-fifth of the total world population, the total number of speakers exceeding 700 000 000) as well as in terms of the total number of languages in the family (more than 70, of which 24 or more enjoy official status and have literary history). Some of the major languages in the family, both in terms of number of native speakers and literary history, are Hindi, Urdu, Bengali (known to its native speakers as Bangla), Assamese, Punjabi, Gujarati, Marathi, and Oriya. Sanskrit, in terms of historical significance and role in the development of modern

Indo-Aryan languages, notwithstanding the very small number of native speakers (only a few hundred), enjoys a very important position within the Indo-Aryan language family. Romani/Romany (popularly known as the 'Gypsy' language), also a language of Indo-Aryan origin, is spoken by several million people in various countries around the world.

Being a region of enormous linguistic diversity, the sociolinguistic situation of South Asia projects a very complex picture. Indo-Aryan languages are in constant and intimate contact with languages belonging to different language families, viz., Tibeto-Burman, Iranian, Dravidian, and Austroasiatic (Munda) languages. In South Asia, from region to region, the accents, dialects, and languages change. The dividing lines between languages are often distorted by large numbers of overlapping and interwoven dialects. It is extremely rare that speakers use only one language; multilingualism is the norm. Speakers often switch between two or more languages. In the context of multilingualism, English, a foreign language, plays a major role. It has a special status in South Asia as a medium of higher education, often associated with social prestige and power. In India, after 54 years of independence, English continues to be the second official language along with Hindi and other official languages. As a result of multilingualism, code switching, and borrowing, most Indo-Aryan languages, especially those of wider communication, have been considerably influenced. This has resulted in the emergence of various mixed languages, pidgins, and creoles. The contact situation has also led to gradual loss of native languages among many regional groups of people.

Distribution of Major Indo-Aryan Languages

Broadly speaking, Modern/New Indo-Aryan (NIA) languages fall into four geographical groups: northwestern, southwestern, midlands, and eastern. The northwestern group includes Sindhi, Punjabi, Lahnda/Lahndi, Pahari, Dogri, Kashmiri, and other Dardic languages. The southwestern language group comprises Gujarati, Marathi, Konkani, Maldivian, and Sinhala (the official language of Sri Lanka). Major languages in the eastern group are Bengali, Assamese, and Oriya. The midlands Indo-Aryan group consists of Hindi and its different dialects, Urdu (the official language of Pakistan) and its various dialects, a variety of dialects known as Eastern and Western Hindi, and many other languages. At the level of the colloquial language spontaneously spoken/heard on radio, television, or other media, and in the schools/colleges of northern India and Pakistan, Hindi and Urdu are virtually one language. They share a single, identical grammatical system and most of the vocabulary. What makes them two distinct languages are their separate writing systems, different borrowing strategies, and a very robust language ideology. For political purposes, they are essentially two languages.

In terms of total number of speakers, Hindi ranks first, with over 337 million speakers (Cardona and Jain, 2003: 4). It is considered to be the third to fifth most widely spoken language in the world. The term 'Hindi belt' refers to the regions of India with major concentrations of Hindi speakers, viz., the states of Bihar, Uttar Pradesh, Rajasthan, Haryana, Himachal Pradesh, Delhi, and Madhya Pradesh. Hindi is also widely spoken in Mumbai, with distinct regional peculiarities. In addition to Hindi, several other native regional languages, very close to Hindi in mutual intelligibility, are spoken in the Hindi belt. Urdu is spoken by approximately 43.4 million people in India, 6.4 million people in Pakistan, and 275 000 people in Bangladesh. It serves as the lingua franca among the Muslims of South Asia living in and outside the subcontinent. In several studies of Hindi dialectology, Urdu has been listed as one of the dialects of 'Hindi,' or Hindustani. Historically, Urdu developed from Khari Boli, or 'Hindavi,' which originated in the Delhi area and was considerably influenced by Kauravi, Hariyanavi, Mevati, eastern Punjabi, and Braj Bhaśa, which, in turn, have developed from the literary language *Śauraseni Apab^{h}-ramśa* of Middle Indo-Aryan.

Other major NIA languages with considerably large number of speakers are Bengali (approximately 69.6 million speakers in India, primarily in West Bengal, and 108.6 million speakers in Bangladesh), Marathi (approximately 62.5 million speakers, mainly spoken in Maharashtra), Gujarati (the language of Gujarat, with approximately 40.67 million speakers), Oriya (the language of Orissa, with approximately 28.06 million speakers), Punjabi (approximately 23.37 million speakers in India, mainly in Punjab but also in several other states, and 50.9 million speakers in Pakistan), Assamese (the language of Assam, with approximately 13.08 million speakers), Sindhi (approximately 9.9 million speakers in Pakistan and 2.12 million speakers in India), Nepali (approximately 2.076 million speakers in India and 9.3 million speakers in Nepal), Konkani (approximately 1.76 million speakers in India) (Cardona and Jain, 2003: 4–5), and Kashmiri (over 4 million speakers in the Jammu & Kashmir state (*Ethnologue*, n.d.).

The NIA languages are primarily spoken in South Asia, except for Romani, the only Indo-Aryan language spoken outside the subcontinent. The Romani language evolved as a result of the migration of a

population of mixed ethnic and linguistic backgrounds from different parts of India. The migration, which started in the 1100s and continued into the 14th century, took this mixed population to several countries, viz., the Byzantine Empire (Greece), Serbia, Croatia, Bulgaria, Romania, Hungary, Germany, France, Rome, Spain, Catalonia, Cyprus, Switzerland, Russia, and the United States (a total population of approximately 12 million people around the world). Despite obvious Iranian and European influence, Romani is built on a central Indo-Aryan core. It has several regional dialects, Vlax being considered as the 'standard' dialect by various scholars.

Historical Development

The Indo-Aryan language group is a major branch of the Indo-Iranian language subfamily, constituting the easternmost group within the Indo-European language family. Research on Indo-Aryan languages leading to the discovery of their relationship to the rest of the languages in the Indo-European family represents a major breakthrough in historical and comparative linguistics. The development of Indo-Aryan languages can be traced back to a continuous span of at least 3500 years (Masica, 1991), although many scholars argue for a much earlier date of origin. The period is broadly divided into three stages: Old Indo-Aryan (c. 1500 to 600 B.C.), Middle Indo-Aryan (c. 600 B.C. to A.D. 1000), and Modern/New Indo-Aryan (A.D. 1000 onward) (Masica, 1991).

Based on their geographical distribution, Middle Indo-Aryan (MIA) dialects are classified into four main groups that developed into the present-day NIA languages: northwestern, southwestern, midlands, and eastern. In terms of phonological changes, the most conservative group consists of the northwestern dialects of the MIA, which have retained many of the Old Indo-Aryan (OIA) features and even some Indo-Iranian ones not attested in OIA. To this group belong languages such as Punjabi, Sindhi, Lahnda, Pahari, and many languages of the Dardic group, including Kashmiri. Some of the most characteristic features with respect to the phonological system of the northwestern group include retention of three sibilants (palatal *ś*, dental *s*, and retroflex *ṣ*) of the OIA. In many languages, these have merged into *s* or *s* and *ś*; the distinction between the OIA liquids *l* and *r* has also been maintained only in certain northwestern (Shahbazgarhi and Mansehra) and in western (Girnar) groups, whereas elsewhere, they merged with *l*. The most advanced group is the eastern dialect of MIA, which has undergone the greatest number of changes.

The oldest and the best contemporary records of MIA are the Aśokan inscriptions (3rd century B.C.) in various dialects written in Kharoṣṭhī on rock edicts (e.g., Mansehra and Shahbazgarhi versions, which represent the northwestern dialects). Owing to certain changes peculiar to the dialects, the terms *Pāli* and *Apab^{h}ramśa* have been employed to refer to the Aśokan dialects. *Prakrit* is a general term often used in the context of MIA dialects to refer to the vernacular varieties other than *Pāli* and *Apab^{h}ramśa*. *Pāli*, the language of the Hinayana Buddhist canon and based on a midland dialect (Masica, 1991: 52), and a representative of the early MIA, developed in northern India before 200 B.C. but was produced much later in Sri Lanka, Burma, and Thailand (Masica, 1991: 56). Most advanced literary dialects of the MIA are the *Apab^{h}ramśa* dialects, which form a rich source of literary texts dating back to A.D. 600 and earlier. In opposition to *Pāli*, *Prakrits*, and *Apab^{h}ramśa*, is the more prestigous *Sanskrit* (the term *Sanskrita* means 'adorned/polished/cultured (language)'). No single attested Vedic dialect has been proved to be the predecessor of the Classical Sanskrit.

Indo-Aryan languages represent a source of a rich literary tradition over thousands of years. The first recorded texts, the Vedic hymns, date back to 1500 B.C. Study of grammar occupied a very important position in the ancient Indian educational system. Students had to study Vedas as well as ancillaries to Vedas, the *Vedāṇgas*. The latter included *śikṣa* 'phonetics', *vyākraṇam* 'grammar', *c^{h}andas* 'meter', *niruktam* 'etymology' (i.e., explanation of difficult Vedic words), *jyotiṣam* 'astronomy' (the Vedic calendar), and *kalpaḥ* 'ceremonial' (i.e., prescribing the rituals and laying down the procedures for carrying out sacrifices and other ceremonies) (Subrahmaniam, 1999: 1). Extensive information on the details of OIA of different time periods and areas is available in Vedic recitation in *Prātiśāk^{h}ya* works and in the classic works of ancient Indian grammarians such as Pānini (between the 6th and 4th centuries B.C.) and Patanjalī (2nd century B.C.) (Cardona and Jain, 2003: 7). Pānini's *Aṣṭad^{h}yāyī* is an elaborate treatise on Sanskrit grammar consisting of eight (*aṣṭa*) chapters (*ad^{h}yāya*). There is a total of 4000 *sūtras*, which are algebraic-formula-like grammatical statements and rules traditionally assigned to six types: *samṇa* (definitions of technical terms), *parib^{h}āṣā* (interpretation of grammatical statements), *ad^{h}ikāra* (defining the scope of a grammatical rule), *vid^{h}i* (signifying operational rules of grammar), *niyama* (restricting the scope of *vid^{h}i sūtras*), and *atideśa* (extending the scope of *vid^{h}i sūtras*) (Singh, 1991: 1).

Writing Systems

Two very popular ancient Indo-Aryan writing systems are Kharoṣṭhī and Brāhmi. Whereas Kharoṣṭhī is written from right to left and was widely used in northwest India and Central Asia, Brāhmi is written from left to right and was popular elsewhere. Kharoṣṭhī was in use from the Aśokan period until around the 4th century A.D., and is generally agreed to be a derivation of Aramaic. Several theories have been put forth for the origin of Brāhmi. Although Indian scholars have argued for the indigenous origin of Brāhmi, many Western scholars have assumed Brāhmi to be derived from a Semitic prototype (Masica, 1991: 133). Some archaeologists argue for the emergence of Brāhmi in the 5th century B.C., but with the discovery of the Indus Valley (Harappan) civilization of c. 2500–1800 B.C. in the early 20th century, with its still undeciphered script, a new dimension was added to the question of the actual time of origin for the Brāhmi script. Many scholars now believe Brāhmi to be a derivation of the Harappan script, although some disagree, considering this to be a radical viewpoint.

Most modern Indo-Aryan writing systems have emerged from Brāhmi. The best known contemporary and widely used script that originated from Brāhmi is the Devanāgri/Nāgri script. Devanāgri, in various modified forms, is used to write several languages, including Sanskrit, Hindi, Bengali, Marathi, and Nepali. It is an outcome of several developmental stages following Brāhmi. Shāradā, a close relative of Brāhmi, which was used for writing Kashmiri several centuries ago, has been recently argued by some scholars to be the immediate predecessor of Devanāgri, which is built on the same system and corresponds with Shāradā letter for letter, although the letters have considerably changed in form. Shāradā is closely associated with the Takri alphabet used for writing Punjabi.

Modified forms of Perso-Arabic (Nastālīq) are currently used to write Urdu, Sindhi, Punjabi (Gurmukhi and Nastālīq are the officially recognized scripts for writing Punjabi), Kashmiri, Shina, and Khowar. Perso-Arabic writing systems for Urdu and Kashmiri are officially recognized whereas those for Shina and Khowar are still struggling for recognition. Representation of additional sounds not present in Persian/Arabic is achieved by use of additional diacritics to suit the specific phonemic inventories of different languages. Redundant Arabic graphemes are retained only in the spelling of Arabic or Persian borrowings, as are certain redundant letters of neo-Brāhmi (Masica, 1991: 151). Representation of Indo-Aryan vowels in Perso-Arabic script, however, is slightly problematic, especially in languages with large vowel inventories. Short vowels are not represented in this system. Reading, therefore, is often a stressful exercise for nonnative speakers and sometimes even for the native speakers beginning to read a language. It is difficult to distinguish between /e:/, /ai/, and /i:/ in word-medial position because only one symbol is used to represent all three of these vowels. Similarly, there is only one symbol representing the vowels /u:/, /o:/, and /au/ in postconsonantal position. Official script for Kashmiri is more advanced in this respect. Each vowel of the 16-vowel system is represented differently with the help of particular diacritics that are commonly used in literature and are officially recognized.

In the Maldive Islands, a script called Tana/Thaana is used. This script is argued to be phonologically quite efficient, and, written from right to left, is a complete innovation. Tana employs symbols, some of which are based on Arabic diacritics and numerals (Masica, 1991: 152). Konkani is probably the only language that seriously uses Roman script for writing. Representation of peculiar sounds is achieved by use of diacritics and special writing conventions.

Phonological Characteristics

Various phonetic and phonological changes characteristic of the Indo-Aryan group distinguish it from the Iranian group of the Indo-Iranian language family. These include (1) reduction of final consonant clusters; (2) absence of voiced sibilants (except in certain NIA languages/dialects, for which voiced sibilants resulted at a later stage of development); (3) retention of voiced aspirated stop consonants, thus having a fourfold distinction of stop consonants in terms of manner of articulation (except in the northwestern languages, which were influenced by contact with Iranian languages); (4) retention of /l/ vs. /r/ distinction in Classical Sanskrit and many central and (north-) western languages and dialects of MIA and NIA (In Iranian languages, /l/ and /r/ indiscriminately merged into /r/); and (5) development of retroflex consonants, a possible result of Dravidian influence on Indo-Aryan languages and an innovation in the Indo-European languages (Note that Burushaski, a language isolate spoken in the region between South and Central Asia, also possesses retroflex consonants). OIA typically consists of a large number of two-consonant and three-consonant clusters that occur at initial, medial, and final positions. However, a large number of these clusters are drastically limited in MIA by several phonological operations, including epenthesis or assimilation in place and manner of articulation. OIA final consonants were generally

lost in MIA dialects, with the exception of *m*, which developed into its vocalic counterpart *m̥*, as in Pāli *puttā* from Sanskrit *putrāt* 'son' (ablative singular) and *putrās* 'son' (nominal singular), but Pāli *puttāṁ* from Sanskrit *putram* (Cardona, 1987: 441). Dissimilar consonants were assimilated in interior clusters by progressive or regressive assimilation, depending on the nature of consonants involved. Examples are Pāli *puttā*, *satt^{h}i-*, and *vagga-* from Sanskrit *putrā-*'son', *sakt^{h}i-* 'thigh', and *varga-* 'group' (Cardona, 1987: 441). Another MIA development was fricative weakening or lenition (except in some dialects), primarily in the postconsonantal position (i.e., s > h/C_; e.g., Pāli *b^{h}ikk^{h}u* from OIA *b^{h}ikṣu* 'monk'; the process is accompanied by consonantal assimilation), and also in preconsonantal position, when weakening is accompanied by metathesis and gemination (e.g., Pāli *sukk^{h}a* from OIA *śuṣka*, with intermediate stages of *sukṣa* and *sukha*, respectively, in which the series of changes involve metathesis followed by fricative weakening and gemination, respectively; and Pāli *pupp^{h}a* from OIA *puṣpa* via intermediate stages of *puhpa* and *pupha*, in which the series of changes involve fricative weakening followed by metathesis and gemination, respectively) (Bubenik, 1996: 46). In the later stages of MIA, the OIA geminates that were created as a result of consonantal assimilation (preserved in some dialects, e.g., Pāli) were degeminated. This was accompanied by compensatory lengthening of the preceding short vowel (e.g., OIA *paśyati* 'sees', *śiṣya* 'disciple' > Pāli *passati*, *sissa*, and Ardha Magadhi *pāsai*, *sīsa*), (Bubenik, 1996: 28). Compensatory vowel lengthening is also observed in several NIA languages in which vowel lengthening follows the degemination of MIA geminates, as in Hindi *sāt*, Bengali *śāt*, and Marathi *sāt* from MIA *satta*, resulting from OIA *sapta* 'seven'. Exceptions are Punjabi, Kashmiri, and some northwestern Indo-Aryan languages (e.g., Kashmiri *sat^h* vs. Hindi *sāt* 'seven'). OIA allowed light, heavy, and overweight syllables of the type VC, VCC, and V:CC, respectively. In MIA, long vowels were generally shortened in overweight syllables (V:>V/_CC). For instance, OIA *gātra* 'limb' and *grīṣma* 'summer' were replaced by MIA *gatta* and *gimha*, respectively (Bubenik, 1996: 29). Another way of eliminating heavy syllables in MIA was through epenthesis (e.g., MIA *sūriya* from Sanskrit *sūrya*). In many MIA dialects, the three sibilants, *ś* (palatal), *s* (dental), and *ṣ* (retroflex), merged into dental *s*. The distinction of three sibilants (and sometimes two) was, however, retained in the northwest dialects.

Although a remarkable stability is observed in the phonological system of NIA *vis-à-vis* that of MIA, and hence, OIA, different phonological operations affect both consonantal and vocalic sounds, thus differentiating the phonological systems of different NIA languages. The basic Indo-Aryan system of stops (which is also that of Sanskrit and the OIA) theoretically involves five distinctive articulatory positions of the tongue, namely, **labial**, **dental**, **retroflex** (or '**cerebral**'), **palatal**, and **velar** (for example, /*p t ṭ c k*/). Typical Indo-Aryan stop consonants are distinguished as voiceless vs. voiced (e.g., *p* vs. *b*) consonants, and unaspirated vs. aspirated (e.g., *p* and *b* vs. *p^h* and *b^h*, respectively) consonants. Some of the phonological changes taking place during the MIA stages continued through NIA, but several new developments also occurred. Voiced aspirates were lost in some languages, especially those of the northwest, being replaced by the corresponding voiced unaspirated obstruents (e.g., Kashmiri and Punjabi). In Punjabi, emergence of a tonal system worked as a compensation, whereby the OIA voiced aspirates were devoiced in addition to loss of aspiration. Retroflex consonants were often replaced by corresponding alveolars in many NIA languages, except in certain phonological environments. Some NIA languages and dialects reveal a tendency to replace the Indo-Aryan palatal stop /c/ by a 'dental' or alveolar affricate [ts]. This is observed in Nepali, some dialects of Bengali, certain Rajasthani dialects, Kumauni, many West Pahari dialects, and several others (Masica, 1991: 94). In some languages and dialects, MIA /c/ surfaces as [c] in certain environments (e.g., before front vowels or palatal glide /y/) and as [ts] elsewhere. A further development in certain languages/dialects is a phonemic contrast between /c/ and /ts/, as in Marathi, Konkani, some West Pahari dialects, and Kashmiri. A step further is realized in the Southern Mewari dialect of Rajasthani, the Chittagong dialect of Bengali, and Assamese, in which the [ts] representation of /c/ is replaced by [s], thus, reducing the phonemic inventory. Palatalized consonants have developed in Kashmiri and some Dardic languages. A complete range of five phonemic nasals (labial /m/, dental /n/, retroflex /ɳ/, palatal /ɲ/, and velar /ŋ/) is found in Dogri, Kalasha, Shina, Sindhi, and some other languages (Masica, 1991: 95). However, in most other languages in this group, many of the different articulatory positions of nasals are often phonologically conditioned. The most frequently occurring nasals are /m/ and /n/. Phonemic palatal nasal /ɲ/ is found in Kashmiri, in which it is a result of a phonologically conditioned diachronic change whereby the palatal vowel inducing palatalization was eventually lost. Although most MIA dialects (except certain northwestern and some central dialects) had lost the distinction between the OIA liquids /l/ and /r/ (they merged with either /l/ (Eastern dialect) or with /r/),

all NIA languages have both /l/ and /r/ sounds. Certain languages, such as Oriya, Gujarati, many varieties of Rajasthani, Bhili, Punjabi, and some dialects of Lahnda, have developed a retroflex version of the lateral ɭ. Retroflex flap [ɽ] has often been taken as an allophonic variant of /ɖ/ in certain environments in many languages and in certain dialects of some languages. In some rural varieties of Kashmiri, /r/ surfaces as retroflex [ɽ] or even as [ɖ] intervocalically, whereas in Standard Kashmiri, the same phoneme surfaces as [r] in all phonological environments (e.g., [koːɽi]/[koːɖi] vs. [koːri] 'girls'). Most Eastern NIA (Magadhan) languages have lost the phonemic contrast between *ś* and *s*, but in some traces these are still seen in free variations of [ś] and [s]. A two-way distinction of *ś* vs. *s* is found in certain languages only in specific environments. In certain dialects of Maithili, for example, [s] occurs before back vowels and [ś] occurs before front vowels, whereas *ś/s* phonemic contrast is observed before central vowels (e.g., *śālu* 'a variety of grain sorghum' vs. *sālu* 'hedgehog') (Masica, 1991: 98). Typically, there are two semivowels in NIA languages – palatal /y/ and labial /v/. In a number of languages, the occurrence of the semivowels is restricted to semi-predictable intervocalic glides. Their position is weakest in eastern Indo-Aryan and strongest in western Indo-Aryan. There is a phonetic as well as an historical difference between the eastern glides, late in origin and sometimes optional, and western preservations of original OIA semivowels. In many NIA languages, /v/ has a distinctive *w*-like allophone occurring before round vowels (the contact between the upper teeth and the inside of the lower lip in *v* is a loose one).

The basic OIA vowel system is a 10-vowel system constituted of *a*, *aː*, *i*, *iː*, *u*, *uː*, *e*, *o*, *aiː*, and *auː*. As a result of various phonological changes during the history of their development, most NIA languages possess vowel systems considerably different from each other as well as from the OIA vowel system. The minimal NIA vowel system consists of six vowels, which falls into two types: the *Oriya type* (/*i e a ɔ o u*/) and the *Nepali/Marathi type* (/*i e*; *a ə*; *o u*/). The latter vowels also occur in Lamani and Sadani (Masica, 1991: 109). There are differences in vowel quality, height, etc., of the corresponding vowels in different languages. Bengali has a seven-vowel system, with an additional /æ/ added to the Oriya type vowels. Other vowel systems are the eight-vowel systems of Gujarati (/*i e ɛ*; *a ə*; *ɔ o u*/) and Assamese (/*i e ɛ a; ɒ ɔ o u*/); the nine-vowel systems of Dogri, Rudhari, Sairaki, and several West Pahari dialects; and the 10-vowel systems of Hindi and Punjabi (/*i iː e œ; a ə; ɔ o u uː*/). The Hindi and Punjabi systems are closest to OIA and are thus considered be the typical Indo-Aryan vowel system: historically, the OIA diphthongs /*ai*/ and /*au*/ were monophthongized into long vowels /*æ*/ and /*ɔ*/ at a much later stage of development and are often represented as /*ai*/ and /*au*/ (*ai* and *au* are retained in some dialects). Additional vowel systems include the 11-vowel systems of Padari, Bhadrawahi, Kumauni, and Konkani, with varying modifications, and the 12- to 13-vowel systems of Braj, Bundeli, some dialects of West Pahari, and Bashkarik (Masica, 1991: 112). There are languages with even larger vowel systems. For example, Kashmiri has a 16-vowel system consisting of front vowels /*i iː e eː ɛ*/, central vowels /*ɨ ɨː ə əː a aː*/, and back vowels /*ʉ uː o oː ɔ*/, with three contrasts in height (high, mid, and low). Up to 20 vowels are found in some Dardic languages. Most NIA languages have nasalized vowels. These vowels are predictable in some languages (in the vicinity of nasal consonants) but in others they are contrastive/phonemic in nature. Certain languages have also developed a tonal system, such as Punjabi (prosodic tone), Lahnda, Dogri, some West Pahari dialects (Khalashi, Kochi, Rudhari), some Dardic languages (e.g., Khowar, Shina, Gawarbati), and Dacca Bengali. Stress in NIA is generally predictable and the position of stress is fixed, although stress patterns may considerably differ from language to language in terms of complexity of rules/constraints determining stress.

Morphosyntax

Old Indo-Aryan verb morphology exhibits tendencies toward simplification. The aspectual system is much reduced. Within the tense system, the distinction between formal perfect and imperfect is eliminated, leading to a two-way contrast in the preterit from the original three-way contrast. The modal system also went through simplification, so that the subjunctive and indicative gradually were eliminated (Cardona and Jain, 2003: 11). Despite such tendencies, the OIA verb system is very rich as compared to the MIA and NIA systems.

During the development of MIA, there was a general leveling down of the rich OIA morphological system by means of various analogical extensions and operations. Contrast between OIA active and medio-passive was lost, as was the contrast between two kinds of future marking in later stages of MIA. Also, distinction among aorist, perfect, and imperfect was generally eliminated. Productive preterit is provided by sigmatic aorist (Cardona, 1987: 444). Because no final consonants are found in MIA, a reduction in the rich declensional system of OIA consonant stems gives rise to a vowel-ending type only. OIA nominals fall into a number of inflectional types, viz., stems ending in *-a*, *-i*, *-u*, *-an*, -C(onsonant), and *-nt*. Although the OIA vocalic

stems remain as such, the consonant ending stems are thematized in the MIA dialects (e.g., Pāli *vijju* < *vidyut* is inflected as an *-u* stem; Pāli *b^{h}aranto* < *b^{h}arant-* is inflected as an *-a* stem) (Bubenik, 1996: 72). In *Ard^{h}a-Magad^{h}i* (AMg), *nt*-stems are thematized (Bubenik, 1996: 67). Thematic stems are remodeled in the MIA dialects (e.g., Sanskrit *devaḥ* (nominative singular) > Pāli *devo*, Sanskrit *devam* (accusative singular) > Pāli *devã*) (Bubenik, 1996: 68). In case of nominal paradigms, although OIA maintains the distinction of singular, plural, and dual categories, there is a complete loss of the dual category in MIA. This is also evident in most NIA languages.

The extensive case inventory of OIA was considerably reduced in MIA, especially in later stages. The OIA dative merged with the genitive, and in late MIA, there was merger of the instrumental case with the locative (Bubenik, 1996: 69). Further down the lines of development, nominal paradigms dichotomized into direct (nominative, accusative) and indirect cases, which eventually fused together, providing the groundwork for the NIA oblique case (e.g., in *Apab^h-ramśa*). Toward its development into NIA, the MIA clitics system also dichotomized into one direct and one oblique form. The oblique form is only used with postpositions (e.g., Hindi/Urdu *-ā* 'NOM.SG' vs. *-e* 'OBL.SG'; Hindi/Urdu *-e* 'NOM.PL' vs. *-õ* 'OBL.PL'). In the system of pronominal clitics, the formal distinction between the direct and oblique forms is found only in OIA and Pāli. Such distinction was lost in some dialects of the MIA (Bubenik, 1996: 90). OIA nominals also had a three-way distinction in gender features, viz., masculine, feminine, and neuter. Although Pāli preserved the three-way distinction of gender, many MIA dialects underwent a gradual simplification in the alignment of three genders. A thematic neuter gender marker was a common target for leveling, which was reassigned masculine ('default') gender in *Ard^{h}a-Magad^{h}i*, for example. Leveling was achieved by various series of phonological changes in different gender marking endings (e.g., shortening of final long vowels, deletion of final consonants, convergence of various kinds of stems, and other phonological changes). With a few exceptions, such as Gujarati, which retained the OIA distinction of masculine, feminine, and neuter gender, most NIA languages have only masculine and feminine distinctions. In case of nominal declension, some of the forms were lost in MIA. These were replaced by the corresponding pronominal forms, resulting in identical declension for nominals and pronominals, as in OIA *devaḥ* (nominal declension) vs. Pāli *devo* (nominal declension) and *so* (pronominal declension) (Bubenik, 1996: 92). Another morphological change characteristic of MIA is the resegmentation of inherited causatives (Bubenik, 1996: 120).

Different changes in the syntactic system led to the development of an ergative syntax in NIA. In many NIA languages, the perfective is semiergative. In ergative constructions in most NIA languages, agreement between the subject and the verb is blocked. Although typical Indo-Aryan languages show subject-object-verb word order, an exception is Kashmiri, which is a verb-second language, with the inflected verb occupying the second position of the clause.

Indo-European Languages

N E Collinge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

Cross-linguistic comparison of words and phrases had already become fashionable in the 17th and 18th centuries. In 1786 Sir William Jones famously postulated the kinship of Sanskrit, Greek, and Latin (and possibly the Germanic and Celtic languages), a grouping to which in 1813 Thomas Young gave the title 'Indo-European' (IE) (although the Germans long preferred 'Indogermanisch'). In 1816 specific historical studies appeared, some by Raynouard on the Romance languages (descendants of Latin) and others by Bopp, who added Avestan and Lithuanian to Jones's list. From Grimm's 1822 work on, geneticism flourished and until the 1870s remained Sanskritocentric (but see section on analogy). The tally of IE languages came to include two that apparently stood alone (despite their internal dialectal splits) – Albanian and Armenian – and six subgroups: Balto-Slavic, Celtic, Germanic, Indo-Iranian, Italic, and Greek. To these were later added two Asian members: Tocharian in 1893 and Hittite in 1917, the latter together with Palaic and Luwian (for sure) and Carian and Lycian (almost certainly) forming the 'Anatolian' subgroup. The status of one or two tongues is still debated: Lycian, Phrygian, and 'Illyrian.' With all these and their descendants taken into account, the current total of known IE languages is around 140 (Collinge, 1995a).

Comparative Reconstruction of the Indo-European Language Family Tree

Comparative reconstruction of the family began with linguists using the following techniques.

1. Interlingual comparison of the categories and structures of grammar (done first by Bopp) is usually considered central. This sector is by and large the least subject to outside influence, although some internal alterations have to be discounted (for example, the changing of lexical elements into grammatical forms); and shifts of even the basic type of syntax do occur (see later section on typology). Phonology then long took first place (after Rask, 1818; and Grimm, 1822); this is understandable, as speech sounds are anatomically limited and their shifts easier to plot. Now, however, 'lexical diffusion' is recognized: sound changes occur more quickly in words of certain types and frequency and later spreading.
2. August Schleicher was first to regularize the use of the family tree (borrowed from scientists) to display descent-relations. He also insisted that 'proto' forms (the theoretically established items of a no-longer-extant parent language) be recognizable, and he standardized the marking of them with a prefixed asterisk.
3. It has long been realized that a compared language's evidence must first be cleansed by removing those changed items whose shifts are quite internal to that language and whose earlier shape is diagnosable by 'internal reconstruction.'
4. Possibly the most salutary control is that of 'uniformitarianism,' first proposed by James Hutton in a lecture in 1785. This rules, to cite its negative aspect, that hypotheses as to past entities and behavior must not venture outside the range of historically testified examples.
5. In the 1870s the 'Neogrammarians' (see Collinge, 1995a: 204–205) made their contribution, which still merits a mention. They outlawed those comparative statements of item change that ignored manifold nonconformities. Shifts must be exceptionless (though they accepted analogy as an interfering force; see later section on analogy). This corrective was necessary at the time; since then, many valid accounts of apparently irregular change have been offered, and causation (which they ignored) has been examined.

Revisions to Indo-European Language Theories

Following these developments in the classification of IE languages were a long succession of revisions and discoveries, some helpful, others disturbing, a few still to be finally assessed.

First among the helpful stands the identification by numerous scholars of 'analogy' as a cause or steerer of change. More particular were the increasingly precise analyses of the original phonology of proto-Indo-European (PIE). Its velar consonants were found (Ascoli, 1870) to be of varied sorts. Then several scholars realized that a local palatalizing effect, once recognized outside Sanskrit, established */e, a, o/* as the true set of original lower vowels.

Brugmann (1876) noted how 'sonant' root consonants (nasals, to which Osthoff added liquids) might within words become vocalized or accompanied by inset vowels. Next, the high vowels */i, u/* were seen as likely to become consonantal */j, w/* in the right context and were in fact 'semivowels.'

Perhaps most striking was the discovery – following a hint by Saussure – that PIE had possessed some deep guttural sounds (vaguely 'laryngeals'), which outside

Anatolian were themselves lost but were replaced by lengthening of neighboring vowels or the insertion of a vocalic element into the syllable.

Theories of Historical Language Change

The earliest disturbing theory was that of Johannes Schmidt (1872), following an idea of Schuchardt's, that historical changes moved like waves across a body of water, being possibly wider, of varying strength, and less adjacent than tree-branching suggests. Sapir (1921) recognized 'drift' as shifts that are certain to occur independently sooner or later in any language.

Again, arrays of apparently distinct shifts within a language may be reflexes of one more general feature change ('conspiracy' theory).

Yet another mechanism for relating shifts and fixing them in time is known as 'glottochronology.' Under this theory, divergence of languages from a common stock is timed by counting the number of words, from a list of shared items, no longer found to be cognate. It has been applied again to IE recently, in attempts to precisely date the origin of IE languages, but it has also long been denounced as untrustworthy, because lexical borrowing is the readiest kind of interlingual interference.

Lastly, disturbing for its effects on the family tree, comes the 'glottalic' hypothesis (see Salmons, 1993). This was promoted most keenly by Gamkrelidze and Ivanov (1984) but forcibly rejected by others, notably Baldi (1999). The traditional, but questionable, set of PIE stop consonants has its simple voiced items */b, d, g/* replaced by the glottalized units */p', t', k'/* (aspiration being seen as an unstable additive to the buccal stops). This idea does explain the curious rarity of supposed */b/* in PIE (because */p'/* is phonically awkward), but the apparent prevalence across the extant languages of the realization of these glottalics as plain **voiced** forms is troubling. Moreover, Germanic (and Armenian) would then be isolated as retaining the original voicelessness (in contrast to Grimm).

Other Theories

Some suggestions that may assist the comparative IE historian are still to be finally assessed. Promising was Johanna Nichols's finding (1986) that marking of a grammatical grouping (such as a noun phrase) – whether on the head member or on the dependent or on both or on neither, or a mixture of these – is a conservative feature and so a clue to genetic status.

Indo-European languages are predominantly dependent-marking. There is certainly resistance to change of marking position, so that at least **non**-relatedness, or late relatedness by geographical movement, may be provable. Time and further research should clarify this.

More in fashion at present is the mathematical-cladistic approach. 'Cladistics,' originally a technical term in biology, is the calculus of family relationships based on shared innovations rather than on simply inherited items. It was brought into linguistics first by Hoenigswald (1987). Now the methodology has been computationalized (see Ringe *et al.*, 2002) as a supplement to traditional family tree study. Applied to the tricky problem of IE subgrouping, cladistics has the interesting result of confirming as unusual the behavior and placing of Germanic (see above, on the glottalic theory). Otherwise, the usual tree is re-established, with Anatolian and Tocharian as early departers and the subgroups Greco-Armenian, Balto-Slavic, and Indo-Iranian forming a joint core. Difficulties are still acknowledged.

Remaining Questions Regarding Classification of Indo-European Languages

First, is an agreed-upon IE tree attainable at all? The various subgroups are themselves soundly based and their membership largely agreed upon; but their relative positioning and chronological fixing (for Hoenigswald, their topology and metrics) are yet unsettled. Revised trees are constantly offered.

Second: Does typology help or hinder? Although it might seem that all IE languages should agree in sound-types and syntactical systems, there are notable discrepancies. For example, the contrast between Hittite verbal categories and those of Greek or Latin, or the present syntax of Hindi or Panjabi versus that of Sanskrit. Genetically linked languages do come to differ in grammar, so Ossetic (Osetin) is now very unlike other Iranian languages generally. Understandable are attempts to trace in IE grammar a syntactic type-change sequence 'active'→'ergative' →'accusative' and a reversal in part.

Next is the question of whether it is possible to arrive at a precise date and location for the family's origin. It is doubtful. Russia, the Black Sea region, and even India have been proposed as birthplaces, and fixing a time of birth is most uncertain (see Clackson, 2000: 451). The current fight is between those who favor a starting point 6000 years ago in Eastern Europe and recent adherents of a beginning (based on biological calculation) 8700 years ago in Anatolia (see Gray and Atkinson, 2003).

Fourth, does archeology help? Pointers such as the 'agricultural dispersal' process have been used to co-map the movements of IE people and of their

languages (Renfrew, 1987; but note his 1999 rethinking). The two developments have rarely shown a firm consensus as to timing or relationships. Firmer clues may lurk; the field is open.

Next, what of the theory of 'nostraticism'? Holger Pedersen introduced the term 'nostratic' in 1903 to cover the establishment of a linguistic super-group that included IE. Enthusiasts followed. Greenberg actually sought to put together all even remotely interaccessible tongues, including Japanese and Inuktitut. Indo-European was linked with South (and even North) Caucasian, Sino-Tibetan, or even Na-Dene language families. The evidence offered is mostly of supposed lexical equations, although Greenberg did use a selection of morphological likenesses. The notion caused much opposition and seems now to be out of favor.

There are some quite opposed concepts of developing linguistic relationships. 'Convergence' has been canvassed – that is, likeness in language caused by areal contact of people rather than (or as well as) by genetic descent ('divergence'). Trubetzkoy (1939) pressed it for IE (see also Hock, 1986: 491–498), while others posited it for other families (notably Weinreich, 1968). Later a general periodic analysis was espoused (Dixon, 1997), based on the biological notion of 'punctuated equilibrium.' This proposes that languages in areal contact during periods of equilibrium suffer the relatively minor diffusion of features each to each, which misleads observers into supposing a family connection; then come periods of punctuation, in which whole language splits do occur. This in-and-out sequence justifies family trees where the size of the evidence defends them (as for IE); it also allows undeniable likenesses between members of different families (IE included).

Definitions of Terms

'Indo-European' is the name of the group of tongues deduced by comparative study to be genetically related. The continued suitability of the name may be questioned. Indian evidence is no longer the major source of relevant information it had been, and since the discovery of Tocharian and the Anatolian subgroup, both in Asia, 'European' is less essential. (Possibly the title 'Eurasian' might be substituted?)

'Proto-Indo-European' indicates the purely theoretical form of the ancestral language, which was formulated by reconciling the reflexes perceived in the group's tongues ('comparative reconstruction'). Proto-Indo-European is not itself a totally integrated working language but rather a summary of deductions. Its sources are manifold and involve languages themselves that are somewhat historically tangled. Description of PIE may be 'systematic,' as by Brugmann (1897–1916), who gave a static and optimistic account of its categories and forms, or 'realistic,' as by Gamkrelidze and Ivanov (1984), for whom PIE is unstable and offers a set of stages of development. (For more information on this, see Lehmann, 2003: 245ff.)

Pre-Proto-Indo-European (PPIE) is a title often used to cover all that can be posited about PIE in its earliest pre-diaspora period (Renfrew, 1999: 271, 284). Sometimes it means 'pre-morphological PIE' – that is, a specific stage before the fully organized condition of PIE syntax and morphology (Collinge, 1995b: 4). Some writers have preferred to use the terms 'PIE I,' 'PIE II,' and so forth.

Conclusion

It is noteworthy that a number (almost a hundred) of 'laws' have been formulated to register apparently regular shifts, and their environments, in individual IE languages or sub-groups, or even across the whole family. The scope of these laws (both as to categories and languages) varies widely, and their validity is always subject to challenge.

Indo-Iranian

E Tucker, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

The Indo-Iranian languages are a major subgroup of the Indo-European (IE) language family, comprising on the one hand the languages of IE descent spoken in the Indian subcontinent (Indo-Aryan), on the other hand those spoken in Iran and adjoining regions such as present day Turkey, Tajikistan, and Afghanistan (Iranian). Indo-Aryan and Iranian languages share so many features that differentiate them from languages belonging to other branches of the IE family that they must have undergone a period of development in common at a prehistoric date. This ancestor language midway between IE and the earliest attested Indo-Aryan and Iranian is normally called Indo-Iranian or Proto-Indo-Iranian.

Thanks to the survival of nearly continuous documentation, the history of both Indo-Aryan and Iranian can be traced back for around three millennia. Anatolian is attested earlier, but Indo-Iranian ranks together with Greek as the branch of the IE family with the longest recorded history. Indo-Iranian languages have served as the vehicle for high literary cultures and for the fundamental texts of five major religions (Hinduism, Buddhism, Jainism, Zoroastrianism, Manichaeism).

In the historical period, the development of the Indo-Iranian languages is conventionally divided into three stages (Old, Middle, and New) in both subgroups. Comparison between Old Indo-Aryan (OIA or Old Indic: Vedic and Classical Sanskrit) and Old Iranian (OIr: Avestan and Old Persian) make it possible to reconstruct the principal features of prehistoric Indo-Iranian.

The prehistoric split between the two branches of Indo-Iranian has traditionally been associated with the movement of one group of peoples, the Proto Indo-Aryans into the Indian subcontinent. However, a problem is raised by evidence in 14th century B.C. Hittite texts relating to the kingdom of the Mitanni, whose general population spoke Hurrian but whose rulers bore Indo-Aryan names. Divine names such as Varuṇa and Indra in a Hittite-Mitanni treaty, and numerals such as *aika* 'one' (Skt. *éka-*; contrast OP *aiva-*, Av. *aēuua*), *satta* 'seven' (Skt. *saptá*) and color adjectives *paritannu* and *pinkarannu* (Skt. *palita-* 'grey', *piṅgala-* 'reddish') in a treatise on horse-training, point to Indo-Aryan rather than

The Indo-Iranian languages are a major subgroup of the Indo-European (IE) language family, comprising on the one hand the languages of IE descent spoken in the Indian subcontinent (Indo-Aryan), on the other hand those spoken in Iran and adjoining regions such as present day Turkey, Tajikistan, and Afghanistan (Iranian). Indo-Aryan and Iranian languages share so many features that differentiate them from languages belonging to other branches of the IE family that they must have undergone a period of development in common at a prehistoric date. This ancestor language midway between IE and the earliest attested Indo-Aryan and Iranian is normally called Indo-Iranian or Proto-Indo-Iranian.

Thanks to the survival of nearly continuous documentation, the history of both Indo-Aryan and Iranian can be traced back for around three millennia. Anatolian is attested earlier, but Indo-Iranian ranks together with Greek as the branch of the IE family with the longest recorded history. Indo-Iranian languages have served as the vehicle for high literary cultures and for the fundamental texts of five major religions (Hinduism, Buddhism, Jainism, Zoroastrianism, Manichaeism).

In the historical period, the development of the Indo-Iranian languages is conventionally divided into three stages (Old, Middle, and New) in both subgroups. Comparison between Old Indo-Aryan (OIA or Old Indic: Vedic and Classical Sanskrit) and Old Iranian (OIr: Avestan and Old Persian) make it possible to reconstruct the principal features of prehistoric Indo-Iranian.

The prehistoric split between the two branches of Indo-Iranian has traditionally been associated with the movement of one group of peoples, the Proto Indo-Aryans into the Indian subcontinent. However, a problem is raised by evidence in 14th century B.C. Hittite texts relating to the kingdom of the Mitanni, whose general population spoke Hurrian but whose rulers bore Indo-Aryan names. Divine names such as Varuṇa and Indra in a Hittite-Mitanni treaty, and numerals such as *aika* 'one' (Skt. *éka-*; contrast OP *aiva-*, Av. *aēuua*), *satta* 'seven' (Skt. *saptá*) and color adjectives *paritannu* and *pinkarannu* (Skt. *palita-* 'grey', *piṅgala-* 'reddish') in a treatise on horse-training, point to Indo-Aryan rather than

undifferentiated Indo-Iranian in the Near East in the second millennium B.C. Documented only during the most recent stage of Indo-Iranian, the Nuristani languages (formerly often called Kafiri), which are spoken in present-day northeastern Afghanistan, also raise problems of classification. They have been explained variously as Iranian (but distant from Pashto), as Indo-Aryan, or as belonging to a separate branch of the Indo-Iranian family.

Indo-Iranian Phonology

The Indo-Iranian vowel system consisted of three short vowels **a*, *i*, *u*, their long counterparts **ā*, *ī*, *ū*, and a pair of short and long diphthongs **ai*, *au*, and **āi*, *āu*. There were also two vocalic liquids ** r̥*, *l̥*.

This simple vowel system resulted from the merger of the IE short vowels **e*, *o*, *a* > Ind-Ir.**a* (Skt. *mádhu-*, YAv. *maδu-*'intoxicating drink', cf. Grk. *μέθυ-*; Skt. *dadárśa*, Av. *dādarəsa* 'I have seen', cf. Grk. *δέδορκα*; Skt. *yájate*, Av. *yazaite* 'worships', cf. Grk. *ἄζεται*). However, at the earliest stage of Ind-Ir. the merger was not complete as palatalization occurred before IE**e*. In open syllables, IE**o* > Ind-Ir.**ā* (Brugmann's Law: Skt *dā́ru-*, Av. *dāuru-*'wood', cf. Grk. *δόρυ*) and merged with **ā* < IE**ē*, *ō*, *ā* (Skt. *rāj-*'king', cf. Lat. *rēx*; Skt. *āśú*, Av. *āsu-*'swift', cf. Grk. *ὠκύ-*; Skt., Av., OP *mātar-*'mother'; cf. Lat. *mater-*). Of the IE resonants, which were allophones of **y,v,n.m,r,l* in the parent language, **i*, *u* continued unchanged, the vocalic nasals **n̥*, m̥ > Ind-Ir.**a* (Skt. *saptá,* Av. *hapta* 'seven'; cf. Lat. *septem*), and the vocalic liquids **r̥*, *l̥* were preserved as vowels only in OIA (Skt. *mṛtá̄-* 'dead', cf. Lat. *mortuus*).

Cases of vocalic hiatus in the earliest OIA and OIr. poetic traditions and the quantities of some final vowels suggest that the inherited IE laryngeal phonemes survived in some form into Indo-Iranian (Ved. trisyllabic *vaata-*'wind' <**vaHata-*). The development of **r̥H*, **l̥H* is complicated (>*ir*/*ur* before vowels, >*īr*/*ūr* before consonants in Skt., but >*ar*(*ə*) in Av.: Skt. *tirás*, Av. *tarō* 'across', ppp. *tīrṇá-*'crossed'; Skt. ppp. *pūrṇá-*, Av. *parəna-*'filled'). Between consonants, an inherited laryngeal sometimes vocalized >*-i-* (Skt., OP *pitā* nom. 'father', cf. Grk. πατήρ, Lat. *pater*), but *-i-* from this source is of more restricted occurrence in Iranian than in Indic (OAv. nom. *ptā*, dat. *fəδrōi* 'father'; OAv. *dug(ə)dar-*, YAv. *duγδar-* 'daughter', cf. Skt. *duhitár-*, Grk. *θυγάτηρ*).

Ablaut alternations inherited from the parent language are often continued directly: Skt. *ásti* 'is', *sánti* 'are', Av. *asti*, *hənti*, OP *astiy*, *ha(n)tiy*, cf. Lat. *est*, *sunt* (IE **e*/zero). However, there was a major restructuring of ablaut into a system of quantitative contrasts involving three grades:

lengthened	full	zero
Skt. *rājānam* 'king' (acc.)	*rājan* 'O, king' (voc)	*rājñas* 'of a king'
Skt. *cakāra* 'he has done'	*cakara* 'I have done'	*cakrur* 'they have done'
Av. *srāuuaiieiti* 'makes hear' (pres.)	*sraotā* 'hear!' (aorist)	*sruta-*'heard' (ppp.)

Indo-Iranian had a large number of obstruents: voiced stops, voiced aspirates, voiceless stops, and perhaps also voiceless aspirates:

**b*	**bh*	**p*	**(ph)*
**d*	**dh*	**t*	**(th)*
**j*	**jh*	**c*	
**g*	**gh*	**k*	**(kh)*

All four series existed in Indo-Aryan, but the voiceless aspirates are variously considered to be inherited from IE, or to have developed from clusters of voiceless stop + laryngeal within Indo-Iranian (Skt. *pṛthú-* 'broad' < IE ** pl̥tHu-* 'broad'; Av. nom. *paṇtā̊* < **ponteH-s*, gen. *paϑō*<**pn̥tH-os* 'path'), or to represent innovations within Indo-Aryan only. OIA also shows a series of retroflex stops (*ṭ*, *ṭh*, *ḍ*, *ḍh* and a retroflex nasal), but these are unlikely to have existed in the Indo-Iranian ancestor, as they are not shared by OIr.

The IE labiovelars underwent a very early conditioned split, producing Indo-Iranian palatals before original front vowels (Skt., Av., OP *-ca* 'and', cf. Lat. *-que*; Skt., OP *jīva-* 'alive'; cf. Lat. *vīvus*; Skt. *hánti*, Av. *jaiṇti* 'kills', cf. Hitt. *kuenzi*) and velars elsewhere (Skt. *yákṛt*, Av. *yākarə* 'liver', cf. Grk. *ἧπαρ*; Skt. *gnā́-*, Av. *g(ə)nā-* 'goddess', cf. Grk. *γυνή*; Skt. *gharmá-*, Av. *garəma-* 'heat', cf. Lat. *formus*). On the other hand, the IE palatal stops **ḱ*, *ǵ*, *ǵh* probably developed into affricates in Indo-Iranian, and further developed to OIA *ś*, *j*, *h,* but to sibilants in most of Iranian (Skt. *śatám*, Av. *satəm* 'hundred', cf. Lat. *centum*; Skt. *ájati* 'drives', Av. *azaiti*, cf. Lat. *ago*; Skt. *áṃhas-*, Av. *ązah-* 'distress', cf. Grk. *ἄγχω* 'I throttle').

There was a partial merger of IE **l* with **r*, but not in all varieties of Old Indic (Vedic *raghú-* 'quick', Classical Skt. *laghu-*, cf. Grk. *ἐλαχύ-*, Lat. *levis*), nor completely in Iranian (Av. *rayu-*'quick'; but NPers. *lištan* 'to lick', cf. Grk. *λείχω*).

IE **s* developed four allophones in Indo-Iranian; **s*, **z*, and **š*, *ž* after **r̥*, *r*, *u*, *ū*, *au*, *āu*, *k*, *i*, *ī*, *ai*, *āi* (the RUKI rule). These sibilants are all continued in OIr. where **š* is also found after **p*, *b(h)*, and **s* > *h* before vowels. In OIA **š* > retroflex *ṣ* but **z*, *ž* (>*ẓ*) were lost, the latter with compensatory lengthening of the preceding vowel and retroflection of the following stop (contrast Av. *mižda-*, Skt. *mīḍhá-* 'reward', cf. Grk. *μισθό-*).

Morphology of Nouns and Pronouns

Vedic, Classical Sanskrit, and Avestan show that Indo-Iranian retained the full IE range of eight cases (nominative, accusative, instrumental, dative, ablative, genitive, locative, vocative) and three numbers (singular, dual, plural). The inflections of thematic nouns and adjectives (stems in *-a* <IE**-e/o*) continued those of the IE parent language (masc. sg. **-as*, *-am*, *-ā*, *-āi*, *-āt*, *-asya*, *-ai*, *-a*, etc.) apart from the remodeled gen. pl. in *-ānām*, and a second nom. pl. in **-āsas*, which was of limited distribution. On the other hand, the inflection of *ā-* stems was remodeled under the influence of *ī-* stems at an Indo-Iranian date (sg. **-ās*, *-ām*, *-ayā*, *-āyāi*, *-āyās*, *-āyā(m)*, *-ai*).

Although inflection depended primarily on the type of stem, for non-thematic stems, it also depended to some extent on inherited patterns of accentuation and ablaut: contrast the rare type of closed genitive sg. OAv. *cašmə̄ṇg*(< **cašmán-s*) from *cašman-* 'eye' and the more frequent 'open' type Ved. *aryamṇás* from *aryamán-* 'hospitality'. Even when the Vedic evidence indicates that the accent had become fixed on one syllable, the alternations in ablaut between the suffix and the inflection were continued (from Ved. *tákṣan-*, Av. *tašan-* 'craftsman': acc. sg. Ved. *tákṣāṇam*, Av. *tašānam*; gen., dat. Ved. *tákṣṇas*, *tákṣṇe* Av. *tašnō*, *tašne*). A parallel distinction between 'strong' and 'weak' cases characterized the inflection of many types of Indo-Iranian nominal stems.

Indo-Iranian had a large number of demonstrative pronouns, some of which were also employed in anaphoric function (**sá-/tá-*), and as third person pronouns (**a-*, Skt. *asya*, *asmāi*, etc.; Av. *ahe*, *ahmāi*, etc.). There were some characteristic pronominal inflections, which probably began to spread to pronominal adjectives in Indo-Iranian: e.g., nom. pl. masc. **-ai* (Skt. *té*, Av. *tōi* 'those'; Ved. *anyé*, YAv. *aṅiie*, OP *aniyai-ciy* 'others'). Some demonstratives combined several stems (Skt. nom. sg. *ayám*, *iyám*, *idám*, acc. *imám*, *imā́m*, *idám*, instr. *enā́*, *ayā́*, dat. *asmái*, *asyái*; YAv. nom. sg. *aēm*, *īm*, *imat̰* 'this', etc.). In the personal pronouns, singular and plural were normally based on completely different stems ('you': nom. sg. Skt. *tvám*, OAv. *tuuə̄m*; nom. pl. Skt. *yūyám*, OAv. *yūš*, *yūžə̄m*), and in the oblique cases there were two sets of forms, one accented, the other enclitic ('me': gen. Skt. *máma*, OAv., OP *manā*, dat. Skt. *máhyam*, OAv. *maibiiā*; enclitic gen.-dat. Skt. *me*, OAv. *mōi*, OP *-maiy*).

Verb Morphology

The Indo-Iranian finite verb system was of considerable complexity because of its large number of intersecting categories, of voice, tense, aspect, and mood. Tense/aspect distinctions were expressed by different stems (present, aorist, perfect, and a seldom attested future), and three sets of personal inflections, which distinguished active and middle voice. The augment *a-* (<IE**e-*) was also prefixed to forms indicating past time.

Within these tense/aspect categories, the morphology of the stems varied, particularly in the present, which served as the basis for both present and imperfect tenses. Many more formal types than the 10 classes recognized for Sanskrit by the Indian grammatical tradition may be reconstructed: for instance, thematic presents built with the IE suffix **-ske-/-sko-* (Skt. *pṛcchati*, Av. *pərəsaiti* 'asks'), reduplicated thematic presents (Skt. *tiṣṭhati*, Av. *hištaiti* 'stands'), athematic root presents where the accent remained fixed on the root (Skt. *váste*, OAv. *vastē* 'wears'). In the aorist category, only s-aorists were morphologically distinctive (Skt. *ábhārṣam* 'I brought', *ápaviṣṭa* 'it purified itself'), while the other types, root aorists, *a*-aorists, and reduplicated aorists resembled imperfects. However, in Indo-Iranian individual verbs developed their own individual systems of contrasts.

The perfect, which originally indicated a state (Skt. *jāgā́ra*, Av. *jaγāra* 'is awake') or the result of a past action (Skt. *tatákṣa*, Av. *tataša* 'has fashioned') was regularly characterized by a special set of inflections and reduplication (an inherited exception is Skt. *veda*, OAv. *vaēdā* 'I know').

The moods were indicative, imperative, subjunctive, optative, and the 'injunctive'. From a formal point of view, the injunctive resembled an unaugmented imperfect or aorist, and its original function was to mention an action without specifying time or mood. An important use of the injunctive was in prohibitions with the particle **mā́* (Skt. *mā́*, Av, OP *mā*, cf. Grk. μή). The imperative was characterized by distinctive inflectional endings, subjunctives, and optatives by morphemes that could be added to any tense/aspect stem (subjunctive **-a-*, giving **-ā-* in thematic stems; optative **-yā-/-ī-*, thematic **-ai-*).

The distinction between active and passive was often realized in finite forms merely by the contrast between active and middle endings. However, present stems in *-ya-* and a particular type of intransitive aorist (RV *ádarśi*, *ádṛśran* 'it, they became visible') were also employed with passive value (RV *avāci*, OAv. *auuācī* 'is/has been said'). The most frequent passive form was the ppp. in *-tá-* (< IE **-tó-*), which was destined to become one of the most important elements in the evolution of the verb system in both the Iranian and Indo-Aryan branches.

Syntax

The word order of Indo-Iranian must have been predominantly SOV, but, as the earliest Vedic and Old Avestan poetry shows, there was a large range of possible variations. In prose, genitives and other qualifiers normally preceded the noun that they determined (Skt. *manor jāyā* 'wife of Manu', OP *kurauš puça* 'son of Cyrus'). Enclitic particles, unaccented pronominal forms, etc., occupied second position (Wackernagel's Law), and a string of particles followed the first word of a sentence, which was frequently a 'preverb' as univerbation only took place later. According to Vedic evidence, the finite verb was unaccented in main clauses, but regained its accent in subordinate clauses. Subordination was by means of relative adverbs such as **yád* 'when, since' (Skt. *yát*, YAv. *yat̰*), **yáthā* 'so that, as' (Skt. *yáthā*, YAv. *yaθa*), **yádi* 'if' (Skt. *yádi*, OP *yadiy*) and the relative pronoun **yá-* (< IE **yó-*; Skt., Av. *yá-*), which frequently correlated with a demonstrative pronoun in the main clause.

Nominal compounds were a typical feature of Indo-Iranian sentence structure, but they rarely exceeded two members, whereas in Classical Sanskrit multiple members became regular. Exocentric compounds were particularly frequent (Skt. *ugrábāhu-*, Av. *uγrabāhu-* 'strong-armed', Skt. *ṣaḍakṣá-*, Av. *xšuuaš.aši-* 'six-eyed').

Lexicon

Although there is a substantial amount of inherited IE material common to both branches of Indo-Iranian, it is with respect to their lexicon that Iranian and Indo-Aryan diverge most clearly (a well-known case is OIr. *ātar-* 'fire' versus OIA *ágni-*). However, the speakers designated themselves by the same ethnic (Skt. *āryá-*, OP *ariya-*, YAv. *airiia-*), and a large number of cultural and religious terms appear to date from the Indo-Iranian stage, e.g., Skt. *rátha-*, Av. *raθa-*'chariot', Skt. *yajñá-*, Av. *yasna-* 'worship', Skt. *hótar-*, Av. *zaotar-* 'priest', Skt. *sóma-*, Av. *haoma-*'sacrificial plant'. The latter all have IE etymologies, but there is also a set of such items that belong to common Indo-Iranian, but are unrelated to anything found elsewhere in IE, and may represent prehistoric loans from an unrelated language and culture: *uśíg-*'priest', Av. *usig-*, 'seer', Skt. *maghá-*, OAv. *maga-* 'gift, offering', Skt. *yātú-*, Av. *yātu-* 'magic(ian')'.

Indonesia is the fifth most populous country in the world, numbering about 180 million people in 1992. Stretching across the equator between southeast Asia and Australia, it is an archipelago of thousands of islands where an incredible diversity of languages is found. Grimes (1988) lists 669 languages that are spoken partly or entirely within the Republic of Indonesia. While this number cannot be regarded as a firm count, since only scanty information is available regarding many of these languages, nonetheless it clearly establishes Indonesia's ranking among the countries of the world as second in the number of distinct living languages. (Papua New Guinea is first and Nigeria is third.)

Distribution and Classification of the Languages

The distribution of these hundreds of languages across the country is far from even. There are only a few score languages spoken in western Indonesia, which is very densely populated, while there are hundreds of languages spoken in the more sparsely

Indonesia is the fifth most populous country in the world, numbering about 180 million people in 1992. Stretching across the equator between southeast Asia and Australia, it is an archipelago of thousands of islands where an incredible diversity of languages is found. Grimes (1988) lists 669 languages that are spoken partly or entirely within the Republic of Indonesia. While this number cannot be regarded as a firm count, since only scanty information is available regarding many of these languages, nonetheless it clearly establishes Indonesia's ranking among the countries of the world as second in the number of distinct living languages. (Papua New Guinea is first and Nigeria is third.)

Distribution and Classification of the Languages

The distribution of these hundreds of languages across the country is far from even. There are only a few score languages spoken in western Indonesia, which is very densely populated, while there are hundreds of languages spoken in the more sparsely

populated islands of eastern Indonesia. Thus, the languages of western Indonesia boast many thousands or even millions of speakers, while the majority of languages in eastern Indonesia have only a few hundred to a few thousand speakers. These differences are largely due to differences in topography and degree of civilization. In western Indonesia, societies were already highly developed by 1000 A.D., as evidenced by the historical record of powerful kingdoms, the ruins of magnificent architectural monuments, and an ancient written literature. By contrast, eastern Indonesia in the 1990s was covered by huge expanses of rain forest and swamps (Irian Jaya) or fragmented into hundreds of islands (Moluccas), populated by ethnic groups many of which are either swidden agriculturalists or seminomadic.

Somewhat more than half the indigenous languages spoken in Indonesia belong to the Austronesian, or Malayo–Polynesian, family. The remaining languages are usually classified as Papuan languages, which essentially means 'non-Austronesian,' since these languages do not all belong to a single genetic family. Besides these indigenous languages, there are several Chinese languages spoken by approximately 2 million ethnic Chinese who are scattered throughout the country.

All the languages boasting 1 million or more speakers are Austronesian (aside from Chinese). The following list of these languages is based on Grimes's (1988) estimation of number of speakers:

Javanese (Central Java)	70 million
Sundanese (Sunda) (W. Java)	25 million
Madurese (Madura) (E. Java)	9 million
Minangkabau (W. Sumatra)	6–7 million
Batak languages (N. Sumatra)	5.5 million
Balinese (Bali) (Bali)	3 million
Buginese (Bugis) (S. Sulawesi)	2.5 million
Acehnese (Aceh) (N. Sumatra)	2.2 million
Banjar (Kalimantan)	1.8 million
Sasak (Lombok, Sunda)	1.5 million
Makassarese (Makasar) (S. Sulawesi)	1.5 million
Lampang (Lampung) (S. Sumatra)	1.5 million
Rejang (S.W. Sumatra)	1 million

This list includes neither Indonesian, the national language, nor Malay, the most widespread lingua franca, both of which number millions of speakers. Because of the unique position of these two languages in the life of the country, they will be discussed more fully below.

While the Austronesian languages are spread throughout the entire country, the non-Austronesian languages are concentrated exclusively in eastern Indonesia: 13 on Halmahera Island in the Moluccas, 17 on Timor and neighboring islands, and the vast majority, approximately 200, in Irian Jaya. Although these languages are collectively called Papuan, they are not in fact all genetically related, i.e., they cannot be shown to be descended from a single ancestral language. Scholars have posited a time depth of about 40 000 years for the entrance of the ancestors of the Papuan languages into the area, as compared with a posited time depth of only about 6000 years for Austronesian speakers into Indonesia. Because of the tremendous time depth, it has not been easy to establish genetic relationships for the non-Austronesian languages, and the ones that have been suggested are not as solidly established as those proposed for the Austronesian languages.

Some 60 different genetic families have been posited for the Papuan languages, although not all these families are represented in Indonesia (see Foley, 1986; Wurm, 1975). The best-known and largest of these within Indonesia is the Dani language family, spoken by 270 000 people inhabiting the central highlands of Irian Jaya. Other Papuan languages of Indonesia include Asmat (upward of 50 000 speakers) and Ekari (100 000) in Irian Jaya, Ternate (42 000) in the Moluccas, and Bunak (50 000) in Timor. All the other Papuan languages of Indonesia are spoken by numerically small groups.

Lingua Francas

As expected in a linguistically pluralistic society, lingua francas have always played an important role in intergroup communication. Of all the lingua francas, the most important by far is Malay. For over 1000 years, it has served as the lingua franca in harbors and bazaars throughout Southeast Asia. When the earliest Europeans arrived in the Indonesian archipelago, they found Malay already in widespread use. In each major center of contact, the local languages influenced the Malay spoken there, giving rise to many regional dialects of Malay. These are still widely spoken in the 1990s.

The National Language

During the time of Dutch colonial control (until 1942), the official language was Dutch but, because Malay was more widely known, it became increasingly important both as an administrative language and as a medium of instruction in schools. Riau Malay, the dialect spoken in central Sumatra near Singapore, became the standard. In the early part of the 20th century, Malay became associated with the nationalist movement for independence. In 1928 young

nationalists declared Bahasa Indonesia, their new name for Malay, to be the national language. Their aspirations were not fully realized until independence came in 1945, and Bahasa Indonesia (Indonesian) was decreed to be the national language.

The choice of Indonesian as the national language is sociolinguistically remarkable in that it was at the time the mother tongue of only 5% of the population. However, it was a politically fortuitous choice because it was so strongly associated with nationalism, it was already in widespread use, and it avoided the factionalism that would have resulted had the choice been one of the majority languages, such as Javanese or Sundanese (42 and 15%, respectively, of the population). From the time of independence, the government has been engaged in developing and promoting the Indonesian language. Thousands of words, especially in technical areas, have been introduced, and grammar and spelling have been standardized (see Alisjahbana, 1984). The position of Indonesian in the 1990s is an enviable story of the successful establishment of a single language as the national language in a linguistically pluralistic society. It enjoys great prestige and virtually all citizens aspire to know the language, since it is viewed as the vehicle for upward socioeconomic mobility. It is the official language of government, education, and mass communication.

Multilingualism and the Status of Minority Languages

The rich linguistic diversity of Indonesia is respected in its constitution, which obliges the state to support the maintenance of the 'regional languages.' Thus the place of minority languages in the life of the people is officially honored. The Ministry of Education and Culture permits education in the mother tongue through the third primary school level, so long as Indonesian is simultaneously being taught to prepare students for instruction exclusively in Indonesian from the fourth primary level onward. Journalism and broadcasting sometimes employ a regional language. The government, however, has thus far not embarked on major programs to develop the minority languages. Nonetheless, these languages continue to flourish because Indonesian is still the mother tongue of only a minority.

In this country where most people speak more than one language, diglossia is widespread. In a typical diglossic situation, the mother tongue is used for 'low' speech functions such as conversation with family and friends, folklore, and cultural events, while Indonesian is used for 'high' speech functions such as official communications, school, and interaction with the government. Since many people have not yet mastered standard Indonesian, they sometimes mix Indonesian with regional Malay for 'high' speech functions.

Literacy

In 1978 it was estimated that 26% of the population between ages 10 and 45 was illiterate. Due to the expansion of the education system, by 1986 the Indonesian government reported only 10% illiteracy among the same age group. These statistics assess only basic literacy, defined as the ability to read the Latin alphabet and Arabic numerals. Statistics for functional literacy or median reading levels are unavailable.

Infancy: Phonological Development

C Stoel-Gammon, University of Washington, Seattle, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

This article provides an overview of phonological development with a focus on production patterns occurring between birth and three years, during which the majority of development occurs. General requirements of phonological acquisition are discussed briefly, followed by a description of prelinguistic vocal development, the transition to speech, and phonological characteristics of first words. Phonetic inventories and error patterns of children acquiring English are discussed.

Phonological Development: What Is Learned?

Within linguistics, the branch of phonology involves the study of sound systems, often in reference to the system of a particular language. A description of the phonological system includes the phonemes and allophones of the language, the phonotactic patterns affecting permitted sequences of phonemes within words, and the suprasegmental features of stress, tone, and timing, among other features. There is a long-standing debate as to which aspects of phonology are 'learned' and which are innate; a full discussion of this issue is beyond the scope of this article. It is clear, however, that acquisition of the phonological system of a language involves knowledge (implicit or explicit) of the phonological properties of that language, phonological representations of the words of the language, and mastery of the articulatory and phonatory gestures associated with adult-like pronunciation of these words. Thus, phonological acquisition involves both cognitive–linguistic learning and the development of the speech-motor skills needed for production.

A key aspect of the cognitive aspect of phonological learning revolves around 'mental' representations that are stored and accessed in the encoding and decoding of words. In spite of a good deal of research regarding the nature and complexity of these representations, key questions remain unanswered, including:

1. Does the child have an auditory representation for word recognition (a form that is presumably close to the adult form) and an articulatory representation for production (a form that may be quite different from the adult form)?
2. If there is a single representation for both perception and production, how are auditory and articulatory features linked within that representation?
3. What is the 'unit' of storage in mental representations? Phonemes? Features? Syllables? Words? Some combination of these?
4. Do the units of storage change as vocabulary grows?
5. Is the mental representation relatively abstract, containing only essential segmental/suprasegmental information, or is phonetic detail included?
6. Are suprasegmental features such as stress and timing included as part of the representation, or are these features coded as 'rules' that apply during word production?
7. How do children's incorrect productions influence their mental representations?
8. Do mental representations change as new words are added to the receptive and productive lexicon?

It should be noted that some of these questions are not unique to the study of developmental phonology. In spite of years of theoretical and experimental research by psychologists, linguists, and speech scientists, there is a lack of consensus on the nature (and number) of mental representations in adult speakers. It is agreed, however, that some type of mental representation is necessary for the perception and production of words. To understand the word *cat*, for example, an individual must have a stored version of the sound sequence associated with the word; the individual must be able to differentiate the word *cat* from similar sounding words, such as *hat, cap, cut,* and *kite*, among others. In a similar manner, production of the word *cat* involves knowledge of the target sound sequence and the articulatory movements needed to distinguish it from other words with similar sound patterns.

Speech Perception

Several months before they produce their first words, infants can recognize words from the ambient language, indicating that they have some sort of storage for those words. Research on infant speech perception has shown that many aspects of phonological learning occur before the comprehension of words (Jusczyk, 1996). In the first 6 months of life, infants demonstrate a remarkable ability to discriminate speech sounds from a variety of languages. After 6 months, discrimination abilities decline and language-specific sensitivity increases. Thus, infants exposed to English can detect the difference between dental and retroflex /t/ phonemes of Hindi at 6 months but not at 12 months. Increased sensitivity to the sound patterns of the input language is apparent not only at the segmental level, but also with regard to phonotactic patterns and prosodic features. Research shows that

infants pay attention to statistical properties of the language they hear, recognizing permissible sequences and frequency of occurrence of phonological features in the input.

Research on infant perception highlights the large gap between perception and speech production in infancy: even before babies utter their first words, many aspects of the perceptual system are nearly adult-like. A major challenge during the period of early acquisition, then, is to learn to **produce** speech so that it resembles the speech the child hears. For instance, a child acquiring English must learn to block the air stream completely for stop consonants and to block it partially for fricatives; to raise the velum for nonnasal consonants and vowels and lower it for nasals; to position the tongue so that it touches the alveolar ridge to make /s/; to begin vocal fold vibration 50 ms (or more) after release of closure to produce initial /p/; and to lower the sides of the tongue to produce /l/. Some of this speech-motor learning occurs prior to the onset of meaningful speech, as shown in the overview of prelinguistic development provided here.

Prelinguistic Development

In the first 12 months, the infant produces a wide variety of vocalizations; some of these are 'speech-like' in that they share features of adult productions, while others, like coughs or burps, bear little resemblance to speech. By definition, 'prelinguistic' vocalizations are non-meaningful, even though they may resemble real words. Thus, productions of [mama] or [dædæ] at 7 months, though sometimes interpreted as attempts to produce *mommy* and *daddy*, are classified as prelinguistic vocalizations unless it can be shown that they have the stable sound-meaning relationships of conventional adult-based words. Word production lags behind comprehension by several months: around 9 months, infants begin to demonstrate limited comprehension of words and simple phrases in particular contexts; by 12 months, the average receptive vocabulary is around 50 words according to parental report (Fensen *et al.*, 1993). First words typically appear between 11 and 14 months, with an average onset of 12 months.

Ages and Stages in the Prelinguistic Period

Most vocal productions in the first month of life are classified as reflexive vocalizations (e.g., cries, coughs, and hiccups) and are thought to be automatic responses reflecting the physical state of the infant. In contrast, nonreflexive vocalizations (e.g., cooing, babbling, and playful yelling and screaming) are productions containing some of the phonetic features found in adult languages (Oller, 2000). Nonreflexive vocalizations pass through a sequence of developmental stages, beginning with vowel-like utterances at 2 months and progressing through a period of vocal play to productions of sequences of consonant–vowel strings toward the end of the first year. All infants, in all linguistic communities, pass through the same stages of early vocal development. Although called 'stages,' the periods are not discrete, and vocalizations from previous stages continue to be used in subsequent ones. The onset of a new stage is marked by the appearance of vocal behaviors not observed (or observed only rarely) in the preceding period; the new behaviors do not necessarily constitute the most frequent vocalization type during that stage.

Stage 1 (0 to 2 Months): Phonation

The first stage is characterized by productions that bear little resemblance to speech. The vocal behaviors of this stage consist primarily of reflexive (sometimes called 'vegetative') vocalizations, such as crying, fussing, coughing, sneezing, and burping. These vocal types are referred to as 'reflexive' because they involve automatic, involuntary motor patterns. Some nonreflexive vowel-like productions occur at this stage.

Stage 2 (2 to 4 Months): Cooing

This stage is characterized by a new type of vocal production that occurs as infants begin smiling and interacting with adults in their environment. 'Coos' are characterized by nasal resonance and are generally perceived as containing vowels and consonants produced at the back of the mouth (velars, uvulars) and back vowels. Consonant–vowel syllables occurring in this period lack the timing of opening and closure gestures found in syllable timing of adult speech.

Stage 3 (4 to 6 Months): Vocal Play

Although the vocalizations of the previous period still occur, new productions in this stage range from repetitions of vowel-like elements to squeals, growls, yells, raspberries (bilabial or labiolingual trills), and friction noises. It seems as though infants are intentionally exploring the capabilities of the vocal tract. The predominant type of vocalization may vary from week to week or even from day to day, making it difficult to characterize an infant's productions without an extensive sample. During this period the infant produces some consonant–vowel (CV) syllables; however, the timing of the transition between

consonant and vowel is slower than that occurring in adult CV syllables.

Stage 4 (6 to 10 Months): Canonical Babble

This stage is characterized by the appearance of syllables composed of alternating consonants and vowels. These syllables occur as single syllables or as strings of repeated syllables, such as [baba]. Because the timing and phonetic characteristics of these syllables are similar to those of adult speech, the productions may resemble words of the language, e.g., [mamama], [dædæ]. Multisyllabic utterances in this stage are categorized as reduplicated babbles (i.e., strings of identical syllables like [bʌbʌ]) or variegated babbles (syllable strings with varying consonants and vowels, like [bagɪ]). While both types of utterances occur in this stage, reduplicated babble predominates initially, while variegated babble increases after the infant reaches 9 to 10 months of age.

Stage 5 (10 Months and Older): Jargon Babble

This stage of babble, also called 'intonated' babble, often cooccurs with both canonical babbling and with the appearance of words. Jargon babble is characterized by strings of sounds and syllables uttered with a variety of stress and intonational patterns. To many adults, it seems as though children are speaking in whole sentences but are using their 'own' language, rather than the standard language spoken by older children and adults around them.

The Sounds of Babble

The repertoire of speech sounds changes dramatically during the first year of life. In the first 6 months, vowel articulations tend to predominate, and most consonantal sounds are produced in the back of the mouth. With the onset of the canonical babbling stage, there is a shift toward labial and coronal consonants, with frequent occurrences of [m], [b], and [d] in particular. Between 6 and 12 months, the consonantal repertoire expands considerably, but claims that babies produce all the sounds of all languages of the world (Jakobson, 1968) in this period have not been substantiated. In fact, a limited set of phones accounts for the great majority of consonantal sounds produced. According to Locke (1983), the consonants [p b m w t d n j k g h] comprise about 90% of the consonants produced by infants raised in American English–speaking environments. Crosslinguistic research has shown that these same manner classes predominate in the babble of infants raised in all linguistic environments.

In the late stages of the prelinguistic period, infant vocalizations show general effects of the ambient language. Babies gradually stop using sounds that do not occur in the ambient language, such as [h] in French, and their syllables start to acquire the timing and pitch contour of the language around them. Thus, while infants from all language communities tend to produce vocalizations with stops, nasals, and glides, there are systematic differences in the frequency of occurrence of particular sound classes and syllable structures that reflect the proportional use in the linguistic input (Vihman, 1996).

The Transition to Meaningful Speech

First words typically appear during the period of canonical babble, and for the next 7 to 10 months, babble and speech coexist. By the age of 18 months, the proportion of babbled utterances has declined markedly, and words and short phrases begin to predominate. Babble and early words share the same phonetic properties in terms of sound types and syllable shapes (Stoel-Gammon, 1992). The consonants that occur most frequently in canonical babbling – stops, nasals, and glides – are the same sound classes that predominate in early word productions, and the manner classes that are infrequent in babble – namely liquids, fricatives, and affricates – are precisely those that appear later in the acquisition of speech. Moreover, the CV syllable structure that is characteristic of the canonical babbling period is also the most frequent syllabic type in early word productions. Developmentally, the sounds of babble serve as the building blocks for the subsequent production of words.

There is strong evidence linking prelinguistic production patterns with general speech and language skills throughout early childhood, indicating continued influence from the babbling period. Longitudinal studies have shown correlations between (1) the age of onset of canonical babble and the age of onset of meaningful speech; (2) the amount of vocalization at 3 months and vocabulary size at 27 months; (3) the number of CV syllables produced at 12 months and the age at which first words are produced; (4) use of consonants at 12 months and phonological skills at 3 years; and (5) the diversity of syllable and sound types at 6 to 14 months and performance on speech and language tests at 5 years. In each case, more in the prelinguistic period (i.e., more vocalizations at 3 months; more CV syllables at 12 months; more consonants in babble) is linked to better performance on speech and language measures. These correlations provide further support for the view that babbling serves as a foundation for subsequent acquisition of speech and language. Infants who produce a greater number of prelinguistic vocalizations, particularly a greater number of canonical utterances with a variety

of consonants and vowels, have amassed a greater arsenal of 'building blocks' that can be recruited for the production of words.

Development of Articulatory–Auditory Links

Infants are exposed to two types of input during the pre-linguistic period: the speech of those around them and their own productions. Both are crucial for the acquisition of speech. Adult input (often modified in the form of child-directed speech) provides the basis for learning the sound–meaning associations that underlie word meaning. Hearing their own vocal output is also important for children's production of words, as it is the basis for establishing links between oral-motor movements and the resulting acoustic signal. Thus, the 6-month-old who frequently produces the syllable [ba] becomes aware of the tactual and kinesthetic sensations associated with production of this syllable and of the auditory signal that results from the production. Once this step is accomplished, infants must recognize that that the babbled syllable [ba] resembles the adult words *ball*. When these two types of learning have occurred, the prelinguistic form [ba] can serve as the basis for production of the word *ball*.

Speech production has a skill component and, as with any skilled activity, practice increases the control and precision with which a movement is performed. Thus, the more often a baby makes the movements that shape the vocal tract to produce particular sounds and sound sequences, the more automatic those movements become and, ultimately, the easier it is to execute them in producing meaningful speech. Babies who have a large stock of practiced syllables have an advantage in early word acquisition because they have a larger repertoire of phonetic forms to which meaning can be attached (Vihman, 1992).

As noted previously, word production requires awareness of the link between a particular sequence of speech sounds and a particular meaning and the knowledge of the articulatory movements needed to articulate the sequence of sounds that resembles the target. If the sequence of speech sounds is present in the child's babble, as in the case of the nonmeaningful [ba] used subsequently for the word *ball*, the change from babble to speech is minimal in terms of articulation. In contrast, acquisition of a word like *shoe* involves learning not only the link between sound and meaning but also a set of unfamiliar articulatory movements. The disparity in the amount of learning involved in acquiring the words *ball* and *shoe* leads to the prediction that, all other things being equal, target words with phonetic properties that mirror a child's prelinguistic vocalizations will be acquired earlier than words with features (e.g., speech sounds, syllable shapes) that are not present in the prelinguistic repertoire.

Sounds and Syllables of the 'First-Word' Period

The first-word period, from the onset of meaningful speech to acquisition of a 50-word vocabulary, is characterized by a phonetic inventory of simple syllabic structures and a small segmental repertoire. (The term 'phonetic inventory' is used here to describe the elements occurring in a child's productions and does not take into account accuracy of production.) In English, syllable types predominating in the first-word period include CV (consonant–vowel), CVC, and CVCV; in terms of consonantal repertoire, productions are composed primarily of stops, nasals, and glides, with a few fricatives, mainly in word-final position.

Research on first-word production in languages other than English reveals the same general properties in terms of sound classes and syllable structure: in all languages, CV syllables tend to predominate, and stops, nasals, and glides occur frequently. Language-specific influences are apparent, however, in the frequency of occurrence of particular sound classes, syllable types, and stress patterns. For example, children acquiring English produce many CVC words and disyllables with trochaic stress; French-learning children, by comparison, produce more disyllabic forms, more words with iambic stress, and more nasals, all features of French.

In spite of the presence of common production patterns, substantial individual variation does occur, presumably arising from a combination of innate and environmental factors. Individual differences have been noted in a range of domains, including consonantal repertoire in babble, 'favorite' sounds in early words, rate of acquisition, degree of phonetic accuracy, variability of production within and across words, and number and type of errors in word productions.

Beyond First Words

The end of the first-word stage, around 18 months, is signaled by a rapid increase in vocabulary size, an expansion of the repertoire of segments and syllable shapes, and the onset of two-word utterances. By 24 months, the typically developing child learning English has acquired a productive vocabulary of 250 to 350 words and can produce multiple-word sentences. Although the child's phonological system is

far from complete, the basic elements are present: the child can produce words with labial, alveolar, and velar stop consonants, both voiced and voiceless; labial and alveolar nasals; glides; and some voiceless fricatives. In terms of syllable structures, the repertoire includes open and closed syllables that can combine to form disyllabic words. In addition, the average 2-year-old can produce some words with consonant clusters in initial and final positions. Compared with consonants, the vowel repertoire at 24 months is relatively complete, although some lax vowels and the r-colored vowels may be missing. By age 36 months, the phonetic inventory of the typically developing child has expanded to include consonants from all place, manner, and voice classes of English, as well as a variety of syllable and word shapes. Although the productive repertoires of typically developing children may be quite similar at 36 months, the developmental paths leading to the repertoire will vary considerably. For this reason, it is difficult to talk about 'order of acquisition' of phonemes because, in spite of general patterns, there is no fixed order.

With expansion of syllable types and segmental repertoire, accuracy of production improves markedly between 24 and 36 months. A majority of children acquiring English can accurately produce all stops, nasals, and glides, as well as /f/ and /h/ in some word positions (see below); by 42 months, the repertoire of accurate segments, at least in some word positions, has increased to include /s, v, ʃ, tʃ, dʒ, r, l/.

Effects of Word Position, Word Length, and Word Stress

Phonological development involves more than learning accurate storage and production of individual speech sounds; accurate production is heavily influenced by the phonetic context in which the target sound occurs. In English, for example, fricatives, velars, and liquids are likely to appear first in word- (or syllable-) final position. As might be expected, production accuracy is affected by syllable structure, with a singleton consonant less prone to error than the same consonant in the context of a cluster. Thus, /s/ may be produced accurately in the word *sun* but not in the word *spoon* or *star*.

Two more factors that influence segmental production are word length and word stress. In general, words of three or more syllables have more errors in syllabic structure and segmental accuracy than shorter words. Stress patterns of the target language also play a role. Almost all disyllabic words in the lexicon of a 2-year-old acquiring English conform to a trochaic pattern of a strong (or stressed) syllable followed by a weak (unstressed) syllable, as in *BAby, TAble, MOmmy*, *COOkie; DOggie* (where capital letters indicate the stressed syllable). There are occurrences of words with iambic stress (a weak syllable followed by a strong syllable), as in *baLLOON, caNOE, guiTAR*, but words with iambic stress are less frequent and tend to appear later in the child's productive vocabulary. Attempts to produce trochaic and iambic words yield quite different outcomes: trochaic words are produced with two syllables from the early stages; iambic words, in contrast, are often reduced to a single syllable. Resulting forms may include the entire strong syllable, e.g., [nu] for *caNOE*, or the onset of the weak syllable followed by the rime of the second syllable, e.g., [bun] for *baLLOON*. Words of more than two syllables are also affected by stress pattern. In English, the predominant form is reduction of the three-syllable form to a two-syllable trochaic production. For example, in the word *animal*, the medial syllable is omitted, while in the word *baNAna,* the initial syllable is dropped.

Child Productions: Adult Targets

A child's phonological system can be described in two ways: through an independent analysis, i.e., with a focus on the child's productions without reference to the adult model; or via a relational analysis, i.e., comparing the child's production to the adult model. Each type of analysis provides important information. An independent analysis includes a summary of the child's phonetic inventory, i.e., a list of segments, sound classes, syllable and word structures, and suprasegmental patterns in the child's speech. A 'relational' analysis, in contrast, focuses on similarities and differences between the child's pronunciation of a word and the target form.

As most adults are aware, mispronunciations are one of the hallmarks of child speech. In some cases, the mispronunciation is so profound that it is impossible to determine what the child was trying to say; in this case, the child's form is classified as unintelligible. At the age of 2 years, about half of a child's utterances are intelligible (i.e., can be understood by an adult who is not familiar with the child). By the age of 3 years, the level of intelligibility increases to 75%, and by age 4, it is 100%. This does not mean that the child's productions are fully adult-like by age 4; rather, it means that the errors do not interfere with intelligibility. Although the level of intelligibility is closely linked to the child's productive phonology, it can also be influenced by other factors, such as syntactic complexity and pragmatic context.

Differences between a child's production of a word and the adult target can stem from problems in a

number of areas: with perception of the adult input; with storage and/or retrieval of the word form; or with the articulatory movements associated with production. In some cases, several of these 'problems' may be involved in single production. Studies of speech perception in infants and young children, however, indicate that children have relatively accurate perception of target forms; moreover, they are often aware that their production is incorrect. For example, Smith (1973) noted the following exchange with his son:

Father: Say 'jump.'
Child: Dup.
Father: No, 'jump.'
Child: Dup.
Father: No, 'jummmp.'
Child: Only Daddy can say 'dup.'

Comparisons of children's productions and adult targets show that the differences between the two are not random but can be described in terms of phonologically based 'phonological processes' that simplify the target by reducing syllabic complexity or substituting one sound class for another. These processes can be divided into four types: syllable structure processes, substitution processes, assimilation processes, and voicing processes. Examples of each of the types, based on the acquisition of English, are provided below.

Syllable Structure Processes

'Syllable structure processes' affect the overall 'shape' of a syllable or word by omitting one or more elements (segments or syllables) from the target form. The influence of the primitive CV syllable shape, common in babble, can be seen in these examples:

1. Omission of a weak syllable, usually in initial or medial position, from the target form; e.g., *telephone* produced as [tɛfon] or *about* produced [baʊt]
2. Omission of the final consonant of a word, e.g., *dog* produced [da] or *ball* produced [ba]
3. Omission of one or more consonants in a cluster, e.g., *snow* produced as [no] or *ant* produced as [æt]

Substitution Processes

'Substitution processes' involve substitution of one sound class for another. Consonants that appear in the child's form tend to be those occurring in babble and in the early word stage. Examples include:

1. Substitution of stops for target fricatives and affricates, e.g., *see* is produced [ti], *zoo* is [du], and *chin* is [tɪn]. The stop is produced at the same (or nearly the same) place of articulation as the target phoneme.
2. Substitution of alveolar stops for target velar stops, e.g., *key* is produced as [ti] and *go* is produced [do].
3. Substitution of alveolar consonants for target alveolo-palatal consonants, e.g., *shoe* is produced [su] and *juice* is [dzus].
4. Substitution of glides for prevocalic liquids, e.g., *red* is produced [wɛd] and *light* is [jaɪt] or [waɪt].
5. Substitution of vowels for post-vocalic liquids and syllabic liquids, e.g., *door* is produced [dɔə] and *bottle* is produced [badu].

Assimilation Processes

'Assimilation processes' (also referred to 'harmony' processes) affect the segments, primarily the consonants, of a target word by making one consonant more like another. These forms resemble reduplicated syllables of canonical babble and early word forms such as *mommy, daddy,* and *baby.* Examples include:

1. Assimilation of a nonvelar consonant to a velar consonant in the same words, e.g., *dog* is produced [gag]
2. Assimilation of a nonlabial consonant to a labial consonant in the same word, e.g., *boat* is produced [bop]
3. Assimilation of a nonnasal consonant to a nasal consonant in the same words, e.g., *bean* is produced [min]

Context-Sensitive Voicing Processes

'Context-sensitive voicing processes' affect the voicing feature of prevocalic and word-final obstruents. Examples include:

1. Voiceless obstruents (primarily stops) in prevocalic position are produced as their voiced cognate, e.g., *two* is produced [du] and *papa* is produced [baba].
2. Voiced obstruents in word-final position are produced as their voiceless cognate, e.g., *cheese* is produced [tʃis]; *bag* is produced [bæk].

In some cases, a single word may be affected by more than one process. For example, when *table* is produced as [bebu], initial /t/ is assimilated to the following labial and syllabic /l/ is rendered as a vowel; when *surprise* is produced as [pwaɪs], the target form is affected by deletion of the initial weak syllable, by gliding of /r/, and by devoicing of word-final /z/.

The patterns described above have been described within a number of theoretical frameworks, including analyses based on features, phonemes, or

'correspondence' rules; more recently, nonlinear models, connectionist approaches, and optimality theoretic descriptions have appeared. Regardless of the phonological framework, the patterns are the same: word productions tend to be simplified to reflect the basic elements that were used in the prelinguistic stages. In terms of views on phonological acquisition, the primary differences across current phonological theories lies in proposals regarding underlying representations, in the emphasis on prosodic versus segmental aspects of development, and in formal descriptions of differences between child productions and the target form.

Summary and Conclusion

This article has provided a brief description of phonological development from birth to 3 years, with emphasis on production and examples primarily from English. It should be remembered that, for the child, the goal of phonological development is not to learn the phonology of the target language but to learn to recognize words from the input and to produce adult-like forms as output.

Basic production patterns first appear in the prelinguistic period, during which the fundamental articulatory patterns emerge: CV syllable structures and use of stop, nasal, and glide consonants. As children begin to recognize and attempt to produce words, they must move beyond the basic repertoire and learn to produce the phonetic, phonological, and prosodic features of the target language.

Infancy: Sensitivity to Linguistic Form

L Gerken, University of Arizona, Tucson, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

Until recently, much of our understanding of how first language develops has come from children's utterances, and particularly their errors. However, recent work on language development in infants has revealed their remarkable sensitivity to linguistic form, especially as it is embodied in the statistical patterns of their input. This article will outline three domains of sensitivity: phonology, the lexicon, and syntax.

The Development of Phonetic Categories

Although infants in the first months of life appear to be able to discriminate most speech sounds used in the world's languages, adults are not. The groundbreaking research of Werker and colleagues has shown that infants lose their ability to discriminate non-native consonant contrasts, and therefore become more like adults, some time between 8 and 10 months of age (Werker and Tees, 1984). These results are generally taken to indicate that infants have begun to form categories of those speech contrasts that are relevant in their language. What causes infants to form phonetic categories has been a puzzle. We might naïvely assume that infants lose their ability to discriminate sounds that are not in the input. However, such an assumption misses the point that many acoustic differences that are phonemic in one language appear in another language as allophones of a single phoneme. For example, English-speakers have the option of releasing or not releasing and aspirating word final stops. Thus, English-learning infants may be exposed to both released and unreleased stops, but this phonetic difference does not affect meaning in English. The same acoustic difference does affect meaning in Hindi. What causes the English-learning infant and the Hindi-learning infant, both of whom hear variation in aspiration in their input, to treat aspiration differently?

One hypothesis is based on the observation that infants show a decline in non-native consonant discrimination at roughly the period of development that they begin to recognize and produce first words (Best, 1995; Jusczyk, 1985; Lalonde and Werker, 1995; MacKain, 1982; Werker and Pegg, 1992). Perhaps associating word forms with meanings as part of building a lexicon causes learners to focus on which aspects of form are relevant to meaning and which are not. Another hypothesis about the mechanism that underlies infants' focus on the phonetic features that are relevant in the target language concerns their attention to the statistical properties of their input (Jusczyk *et al.*, 1990; Kuhl, 1993; Maye *et al.*, 2002). On this view, an English-learning infant might hear a continuum of different degrees of aspiration on word-final stops, with most of the values clustering around a particular point in the acoustic distribution. That is, English-learning infants are likely to hear a monomodal distribution of aspiration. Hindi-learning infants are also likely to hear a range of aspiration values; however, the values should cluster around two points in the distribution – one for segments in which the speaker intends aspiration and the other for intentionally unaspirated segments. Thus, the Hindi-learner is exposed to a bimodal distribution of this acoustic variable. Recent research by Maye and colleagues using the preferential listening technique suggests that even 6-month-olds respond differently to mono-versus bimodal distributions of speech sounds (Maye *et al.*, 2002).

The Development of the Lexicon

A great deal of research over the past decade has focused on the cues that infants might use to identify potential word forms, and particular, to segment words from the speech stream. Suggested segmentation cues include words produced in isolation (Brent and Siskind, 2001), phrase-final position (e.g., Fernald *et al.*, 2001; Saffran *et al.*, 1996b), language-specific canonical stress patterns (e.g., Echols *et al.*, 1997; Johnson and Jusczyk, 2001; Morgan and Saffran, 1995), phonotactic information (Christophe *et al.*, 1994; Johnson and Jusczyk, 2001), and the probability with which one syllable is followed by another (Jusczyk *et al.*, 1999; Morgan and Saffran, 1995; Saffran *et al.*, 1996a).

Once word candidates have been segmented from the speech stream, they must be compared to existing words in the lexicon. There is some evidence that infants' ability to access stored word representations is highly dependent on there being an acoustic match between the stored word and the currently heard one. For example, infants are better able to recognize words spoken by the same talker at familiarization and test (Houston and Jusczyk, 2003). One topic of current debate in infant lexical development is whether infants gradually become more and more competent at accessing stored word forms (Swingley and Aslin, 2002), or whether there is a discontinuity in lexical representation that occurs when infants begin to associate word forms with referents (Stager and Werker, 1997; Werker *et al.*, 2002).

The Development of Syntax

The first studies examining infants' sensitivity to the syntactic forms of utterances involved making modifications to the language the infant was already learning. Shady *et al.* (1995) demonstrated that 10.5-month-olds could discriminate normal English sentences from sentences in which determiners and nouns were reversed (e.g., "kitten the"). Other studies demonstrated that infants at a similar age could discriminate normal English sentences from those in which a subset of grammatical morphemes (e.g., a, was) were replaced by nonsense syllables (Shafer *et al.*, 1998). Santelmann and Jusczyk (1998) showed that 18-month-olds, but not 15-month-olds, discriminated sentences in which auxiliaries and verb inflections were grammatically correct (e.g., "is running") from sentences with mismatches ("can running").

Other studies have asked what infants are able to learn about the syntax of an artificial language with very brief exposure in the laboratory. Gómez and Gerken (1999) presented 12-month-olds with a subset of strings produced by one of two finite state grammars. Half of the infants were trained for about two minutes on strings from Grammar 1 and half on strings from Grammar 2. During test, both groups of infants heard strings in which new vocabulary was substituted for the syllables in the training grammar (e.g., JED, FIM, TUP, DAK, SOG replaced VOT, PEL, JIC, RUD, TAM, respectively). Infants showed a preference for strings that were consistent with their training grammar, suggesting that they had abstracted some aspect of grammatical structure above and beyond pairs of specific elements. Other researchers (Marcus *et al.*, 1999) found a similar result with 7-month-olds who were exposed to a simpler grammar. In both sets of studies, it is likely that infants were relying on a pattern of repeating and alternating syllables to determine whether what they heard during test was the same as or different from the training stimuli, making the task somewhat different than most aspects of syntax learning.

Still other studies combine learning in the lab with natural language. In one study, 17-month-old English-learning infants were exposed to a Russian gender paradigm with six masculine and six feminine noun stems each appearing with two case endings (Gerken *et al.*, 2005). Two of the feminine and two of the masculine words were withheld during familiarization and presented at test (grammatical items), along with the same stems with the opposite gender case endings (ungrammatical items). Infants discriminate grammatical from ungrammatical items, but only when a subset of the familiarization stimuli contained a second indicator of gender (/k/ on feminine stems and /tɛl/ on masculine stems.

Summary

The studies outlined in this article suggest that infants approach the task of language learning with very sophisticated statistical pattern detection and storage abilities. They raise the possibility that much of the work of language acquisition in the toddler to early school years is to link the language forms noted in infancy with meaning. It remains to be seen whether and how such domain neutral abilities interact with any biological endowment specifically for language.

Abductive reasoning was championed by the early pragmatist Charles Peirce as an empirically focused procedure for the construction of classes and categories from observed data. He defined it as follows:

> The surprising fact, C, is observed; But if A were true, C would be a matter of course, Hence, there is reason to suspect that A is true (Peirce, 1940: 151).

Abduction does not really require that the fact observed be surprising. Peirce's definition of abductive reasoning is presented as a syllogism. We use (a1), (a2) to mark assumptions; '∧' is logical conjunction; and '(c)' is the inferred conclusion of valid reasoning procedure.

(1) (a1) Fact C is observed;
∧ (a2) If A were true, C would be a matter of course;
———
(c) There is a reason to suspect that A is true.

Abductive inferences lead to testable hypotheses about states of affairs. Data are correlated on the basis of their similarity or by analogy with some known system, usually with an eye to their apparent function or relevance within the emerging general description. An example of abductive reasoning in historical linguistics is (2).

(2) (a1) In the ancient Indic language Sanskrit, words for numbers 2–7 are *dva, tri, catur, pañca, ṣaṣ, sapta*. These are similar to number words in European languages known to be related to one another: e.g., Slovak *dva*, Latin *duo* '2'; Slovak *tri*, Italian *tre* '3'; Latin *quattuor* '4'; Welsh *pump*, German *fünf* '5'; Spanish *seis*, English *six* '6'; Latin *septem* '7'.

Inference: Abduction, Induction, Deduction

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

Abductive reasoning was championed by the early pragmatist Charles Peirce as an empirically focused procedure for the construction of classes and categories from observed data. He defined it as follows:

> The surprising fact, C, is observed; But if A were true, C would be a matter of course, Hence, there is reason to suspect that A is true (Peirce, 1940: 151).

Abduction does not really require that the fact observed be surprising. Peirce's definition of abductive reasoning is presented as a syllogism. We use (a1), (a2) to mark assumptions; '∧' is logical conjunction; and '(c)' is the inferred conclusion of valid reasoning procedure.

(1) (a1) Fact C is observed;
∧ (a2) If A were true, C would be a matter of course;
———
(c) There is a reason to suspect that A is true.

Abductive inferences lead to testable hypotheses about states of affairs. Data are correlated on the basis of their similarity or by analogy with some known system, usually with an eye to their apparent function or relevance within the emerging general description. An example of abductive reasoning in historical linguistics is (2).

(2) (a1) In the ancient Indic language Sanskrit, words for numbers 2–7 are *dva, tri, catur, pañca, ṣaṣ, sapta*. These are similar to number words in European languages known to be related to one another: e.g., Slovak *dva*, Latin *duo* '2'; Slovak *tri*, Italian *tre* '3'; Latin *quattuor* '4'; Welsh *pump*, German *fünf* '5'; Spanish *seis*, English *six* '6'; Latin *septem* '7'.

∧ (a2) If Sanskrit were related to these European languages (i.e., they all have a common ancestor), the similarity would be a matter of course.

(c) There is a reason to suspect that Sanskrit is related to European languages.

(2(a1)) collapses several similar observations. We could deconstruct (a1) and (a2) into a series of syllogisms like (3).

(3) (a1) Sanskrit *dva* means '2'
∧ (a2) Slovak *dva* also means '2'

(c) Perhaps Sanskrit is related to Slovak (What other evidence is there?)

(2(a2)) is an imaginative leap because Sanskrit is separated by time and thousands of kilometers from the European languages, and it was spoken by a different race. (2(a2)) expresses the intuition underlying the creation of the hypothesis in (2(c)). The essential contribution of intuition to scientific theory is widely recognized among philosophers of science.

> Pure logic could never lead us to anything but tautologies; it could create nothing new; not from it alone can any science issue. [...T]o make arithmetic, as to make geometry, or to make any science, something else than pure logic is necessary. To designate this something else we have no word other than *intuition*. [... L]ogic and intuition have each their necessary role. Each is indispensable. Logic, which alone can give certainty, is the instrument of demonstration; intuition is the instrument of invention (Poincaré, 1946: 214f., 219).

> The supreme task of the physicist is to arrive at those elementary laws from which the cosmos can be built up by pure deduction. There is no logical path to these laws, only intuition resting on sympathetic understanding of experience can reach them (Einstein, 1973: 221).

The abduced hypothesis (2(c)) can be inductively confirmed by finding additional systematic correspondences leading to the recognition of an Indo-European language family. Once a part of the system is recognized and predictions about the whole system begin to be made, the investigator moves from abduction – hypothesizing – to hypothesis testing and inductive reasoning.

Before Peirce, abduction was included within induction. An example of inductive inference is (4).

(4) (a1) Every day till now the sun has risen in the east.

(c) If we check tomorrow, the sun will have risen in the east.

The inductive inference (4(c)) is a prediction based on sampling; (a1) can be deconstructed into a set of assumptions: *On day 1 the sun rose in the east* ∧ *On day 2 the sun rose in the east* ∧ ... *Yesterday the sun rose in the east* ∧ *This morning the sun rose in the east*. If the sampling technique is good, the prediction will probably be verified: (4(c)) is highly probable given the assumption (4(a1)), but it is not necessarily going to be the case. Inductive inference is used in linguistics: for instance, if you are told that almost all French nouns ending in *-ion* are feminine then you can inductively infer that the next French noun you encounter that ends in *-ion* will most probably be feminine. Induction uncovers tendencies, but not certainties, and so it is open to dispute; so, the problem with inductive reasoning is exactly that it identifies conclusions in which we have some degree of confidence (given the assumptions) but not the kind of confidence that is given to deductions.

Inductivism argues from particular instances to a general hypothesis or model for a universal set of instances (Bacon, 1620 I: 19; Mill, 1970: 188). The inductive method assumes that there is a natural order that can be discovered through rational means by inspecting natural phenomena. If this underlying assumption were correct, the inductivist model would be the only model possible because it is determined by natural order and natural laws; it is a reflection of nature. Inductivist models can be illustrated by Newtonian physics and, because language is a natural phenomenon, American structuralist linguistics: "The only useful generalizations about language are inductive generalizations" (Bloomfield, 1933: 20). But

> There is no inductive method which would lead to the fundamental concepts of physics. Failure to understand this fact constituted the basic philosophical error of so many investigators of the nineteenth century. [...] Logical thinking is necessarily deductive; it is based upon hypothetical concepts and axioms (Einstein, 1973: 299).

In formal semantics and other formal systems deductive reasoning is required because, provided the assumptions are correct and the reasoning process valid, a consistent conclusion is guaranteed. For instance, from any proposition p we can validly deduce p.

(5) (a) Max weighs 250 pounds.

(c) Max weighs 250 pounds.

More interesting deductions involve more than one assumption, e.g., from (a1) *A bachelor is a man who has never married* and (a2) *Max is married*, we can deduce that (c) *Max is not a bachelor*. Even Aristotle did not recognize that this is only true when there is a referent for Max. Aristotle wrote, "When we have proved that an attribute applies to all of a kind, we shall have proved that it belongs to some of the kind"

(*Topics,* 1984: 109ª4). In Aristotle's scheme, it is therefore possible to make the following chain of valid inference: *No horse is a unicorn* → *No unicorn is a horse* → *Some unicorn is not a horse*. The first proposition is true and can be represented in the predicate calculus as $\forall x[Hx \rightarrow \neg Ux]$, and the final proposition has the form $\exists x[Ux \wedge \neg Hx]$, which asserts the existence of unicorns. The conditional $\forall x[Hx \rightarrow \neg Ux] \rightarrow \exists x[Ux \wedge \neg Hx]$ is false if $\exists x[Ux \wedge \neg Hx]$ is false, i.e., when there are no unicorns. Aristotle, like the ordinary language user, assumed the existence of referents for the terms in statements, so for him *No horse is a unicorn* does entail *Some horse is not a unicorn*. An Aristotelian syllogistic is

(6) (a1) All humans are mortal.
∧ (a2) All Greeks are human.

(c) All Greeks are mortal.

If we vary this by making premise (6(a1)) false, *All humans are immortal,* the conclusion must be *All Greeks are immortal* – clearly demonstrating that false assumptions will lead by valid argument to consistent but probably false conclusions. Not always, though:

(7) (a1) All women are cats.
∧ (a2) All cats are human.

(c) All women are human.

It follows that we must get our assumptions right if we are to use deductive inference to seek true conclusions. Note that valid reasoning is defined within a system (a logic), whereas truth is defined in relation to (models of) worlds.

A hypothetico-deductive model, e.g., of language, is the inverse of the inductivist model. Hypothetico-deductivism postulates an abstract general theory of the phenomena in question in terms of a defined vocabulary consisting of a specified set of symbols with an interpretation specified for each vocabulary item; there will also be an explicit syntax consisting of a set of axioms and rules for combining the vocabulary items and a set of axioms and rules for interpreting theorems (i.e., sentences) of the metalanguage. This is why mathematical models of natural phenomena are preferred.

> The essential thing is the aim to represent the multitude of concepts and propositions, close to experience, as propositions, logically deduced from a basis, as narrow as possible, of fundamental concepts and fundamental relations (Einstein, 1973: 287).

The theorems, well-formed formulae, or sentences that output from the model should correspond with real-world data, such as utterances in the object-language. However, the correspondences will have to be evaluated intuitively. There may be no way of ensuring that the linguist's intuitions are good, because it is not known quite what intuition is. In a coming together of all three kinds of inference, it is reasonable to suppose that the kind of data-gathering enterprise carried out by inductivists (which relies on abductivism) creates a corpus that ought to provide the best opportunity for the linguist's intuitions to work on. The corpus will also offer data against which to check the products of any hypothetico-deductive theory a linguist creates.

Linguistic theorizing needs the bottom-up data gathering and preliminary classification from phenomenological inductivism and the top-down hypothesis construction from hypothetico-deductivism. They cannot be related in neat temporal sequence; experience tells us that the linguistic researcher must expect to go to and fro between them, reviewing the data to abduce (intuit) hypotheses, and then checking the hypotheses against the data, using some sort of evaluation procedures. Data needs to be classified using inductivist principles; yet classification and taxonomy deal with abstract objects that are essentially similar to the theoretical constructs of a hypothetico-deductive system. It follows that the inductivist's choice of data, indeed the very perception of the data, involves a categorial process that cannot, in the end, be satisfactorily distinguished from hypothetico-deductivism. We are into a chicken and egg argument if we try to rigidly determine which is prior. The significant lesson is that abductivism, inductivism, and deductivism are complementary, and all are essential to the advancement of linguistic science.

We have looked at three different kinds of inference. Abductive reasoning is used in figuring out classes, categories, and functions of observed phenomena – i.e., arriving at a hypothesis. With abductive reasoning the conclusions are based on a best guess; once predictions are built on the results of abduction, we have induction based on samples of the data (market research is one practical use of induction). Deductive inference is the move from assumptions to valid conclusions by observing strict rules of procedure (identified in systems of logic) that guarantee a valid conclusion from the assumptions by preserving monotonicity (q.v.); the assumptions must be correct if the conclusions are to accord with the facts. As Peirce (1940: 154) says:

> These distinctions [between abductive, inductive, and deductive reasoning] are perfectly clear in principle, which is all that is necessary, although it might sometimes be a nice question to say to which class a given inference belongs.

Any thorough account of natural language understanding uses all three kinds of inference. (It must also recognize defeasible pragmatic inferences of the Gricean kind; see Sperber and Wilson, 1995; Harman, 1999; Levinson, 2000.)

Inflection and Derivation

Introduction

Inflection and derivation are traditional notions in the domain of morphology, the subdiscipline of linguistics that deals with the internal structure of words. Inflection deals with the different forms of a word. For instance, the English words *walk*, *walks*, *walked*, and *walking* are considered different word forms of the lexeme WALK. The notion 'lexeme' is used for the more abstract notion 'word' and is represented by means of small capitals. In a dictionary of English, these four different word forms do not receive separate lexical entries, but are dealt with in one entry, that for the verbal lexeme WALK. The noun *walker*, on the other hand, is not considered as a form of the lexeme WALK, but as a different lexeme, with a different meaning and a different lexical category (it is a noun). It usually has its own lexical entry in a dictionary. The lexeme WALKER is considered to be the product of derivation, the creation of a new lexeme through the application of a morphological process of affixation, the attachment of the suffix *-er* to a base lexeme.

The distinction between inflection and derivation is primarily a functional one: it refers to different functions of morphological processes, the creation of different forms of lexemes versus the creation of different lexemes. The formal means for these different functions may be the same, as is the case for the English examples used here: in both inflection and derivation, use is made of the process of suffixation. Another morphological process that may be used in both inflection and derivation is vowel alternation. For instance, vowel alternation is found in the past tense form of *to fall*, which has the form *fell*. The latter form is also that of the related causative verb for *to fall*, the verb *to fell*. Thus, both inflection and derivation are formally different from compounding, the morphological process in which lexemes are concatenated to form new complex words. The cover term for derivation and compounding is word formation.

The English plural noun *walkers* can be decomposed morphologically as follows: *walk-er-s*. This word consists of the stem *walker* and the plural ending *-s*. Thus, the stem of a word is the word form minus its inflectional markers. The stem *walker* in turn consists of a simplex stem (that is, a root) and

Any thorough account of natural language understanding uses all three kinds of inference. (It must also recognize defeasible pragmatic inferences of the Gricean kind; see Sperber and Wilson, 1995; Harman, 1999; Levinson, 2000.)

Inflection and Derivation

Introduction

Inflection and derivation are traditional notions in the domain of morphology, the subdiscipline of linguistics that deals with the internal structure of words. Inflection deals with the different forms of a word. For instance, the English words *walk*, *walks*, *walked*, and *walking* are considered different word forms of the lexeme WALK. The notion 'lexeme' is used for the more abstract notion 'word' and is represented by means of small capitals. In a dictionary of English, these four different word forms do not receive separate lexical entries, but are dealt with in one entry, that for the verbal lexeme WALK. The noun *walker*, on the other hand, is not considered as a form of the lexeme WALK, but as a different lexeme, with a different meaning and a different lexical category (it is a noun). It usually has its own lexical entry in a dictionary. The lexeme WALKER is considered to be the product of derivation, the creation of a new lexeme through the application of a morphological process of affixation, the attachment of the suffix *-er* to a base lexeme.

The distinction between inflection and derivation is primarily a functional one: it refers to different functions of morphological processes, the creation of different forms of lexemes versus the creation of different lexemes. The formal means for these different functions may be the same, as is the case for the English examples used here: in both inflection and derivation, use is made of the process of suffixation. Another morphological process that may be used in both inflection and derivation is vowel alternation. For instance, vowel alternation is found in the past tense form of *to fall*, which has the form *fell*. The latter form is also that of the related causative verb for *to fall*, the verb *to fell*. Thus, both inflection and derivation are formally different from compounding, the morphological process in which lexemes are concatenated to form new complex words. The cover term for derivation and compounding is word formation.

The English plural noun *walkers* can be decomposed morphologically as follows: *walk-er-s*. This word consists of the stem *walker* and the plural ending *-s*. Thus, the stem of a word is the word form minus its inflectional markers. The stem *walker* in turn consists of a simplex stem (that is, a root) and

the derivational suffix *-er*. The distinction between word and stem is the main formal correlate of the distinction between inflection and derivation. Normally, the creation of new lexemes is performed on the basis of the stem form of a lexeme, not on the basis of one of its inflectional forms. For instance, the Italian noun *macchina* 'car' consists of a stem *macchin-* and an inflectional ending *-a*. The word *macchin-ista* 'driver' is derived by adding the suffix *-ista* to the stem. If we used the full word form *macchina,* the wrong form *macchina-ista* would have been derived.

A consequence of the distinction between inflection and derivation is that we expect inflection to be peripheral to derivation; derivation creates stems from stems, and subsequently, inflection creates concrete word forms from stems. This expectation is confirmed by Greenberg's Universal 28, which reads as follows:

> Universal 28. If both the derivation and the inflection follow the root, or they both precede the root, the derivation is always between the root and the inflection (Greenberg, 1963: 93).

Three different issues concerning the distinction between inflection and derivation are topics of debate among linguists. The first issue is that of the formal criteria for distinguishing between these two notions. How do we know whether a certain morphological process belongs to the domain of inflection or to that of derivation? Is there a sharp boundary between the two categories? The second issue is that linguists have discussed which properties are typical for inflection and which ones for derivation. For instance, it has been claimed that inflection is more productive than derivation. The third issue is that of the position of inflection and derivation in the grammar. Do they belong to the same morphological module of the grammar or are they different modules? These three issues will be dealt with in the following sections of this article.

Formal Criteria

Obligatoriness

A first criterion for distinguishing between inflection and derivation is that inflection is obligatory, whereas derivation is optional. For instance, each English noun must be marked as either singular or plural. Hence, the category number is an obligatory category of English, and hence inflectional. Similarly, in languages with case systems, each noun must be marked for a specific case. In most languages, verbs are marked obligatorily for a specific tense and often for person and number of the subject of the clause. Note that this is true even if there is no overt marking for a particular inflectional feature. For instance, there is no overt number marking for English singular nouns. There are also nouns that, for semantic reasons, do not have plural forms, such as *milk* and *abstractness*. These nouns must nevertheless be considered singular nouns because they trigger singular number agreement with verbs. In contrast, no obligatory morphological expression is involved in using the agent noun for the verb *walk*, that is, the word *walker*, with the suffix *-er* that creates de-verbal agent nouns. The use of this word is a choice made by the language user for purely semantic reasons. Hence, we consider *walker* a case of derivation.

Syntactic Relevance

A second criterion for the demarcation of inflection and derivation is that of syntactic relevance; inflection has been defined as that part of morphology that is relevant to syntax (Anderson, 1992). Particular word forms may be required by syntactic context. This is the case for syntactic configurations in which agreement between constituents is required. The rule of subject–verb agreement in English, for instance, indicates that a specific verb form is required by the subject of the clause, a verb form with the same properties for the categories number and person. In Dutch and German (Standard German), a pre-nominal adjective must agree in gender, number, and definiteness with the nominal phrase of which it forms a part. Noun phrases may have to carry a specific case depending on their syntactic function. In Latin, the subject is marked by nominative case and the direct object by accusative case. In the case of rection (or government), words require a specific form of the words in the phrase that they govern. German prepositions, for instance, require a specific case form of the words in the nominal phrases that they govern.

This does not mean, however, that inflection is always governed by syntax. In Latin, for instance, the accusative form of the word *Roma* 'Rome' is *Romam*. This is the form to be used when this noun functions as the direct object of a clause, but it can also function as an adverbial phrase, with the meaning 'to Rome.' In the latter case, the accusative form is not required by syntactic context, but a choice made by the language user in order to express a particular piece of information. This is called semantic case. The same applies to the use of plural number for the noun BOOK in *John read these books*. The choice for the plural form of *book* is not dictated by the syntactic context.

It should be realized, however, that one cannot claim that derivation has no relevance to syntax whatsoever. Since derivation may indicate a change of syntactic category, this fact in itself is already of relevance to syntax. In the case of derivation of verbs, the derived verb may also have a specific syntactic

valence. For instance, the derivation of causative verbs leads to the creation of transitive verbs that indicate the obligatory presence of a direct object, as in *John whitened the walls*. Hence, the derivation of causative verbs has syntactic relevance. The difference with inflection is that the choice of a particular derived word is not governed by syntactic context.

Change of Syntactic Category

A third criterion of demarcation is that derivation may change the syntactic category of its input forms, whereas inflection is always category-neutral. This criterion reflects the idea that inflection creates forms of the same lexeme, unlike derivation, which determines the lexical category of the lexemes it creates. For instance, the Dutch diminutive suffix -(*t*)*je* is considered to be a derivational suffix since it always creates nouns, whatever the lexical category of its input: *hond* 'N, dog' - *hond-je* 'N, doggy'; *blond* 'A, blond' - *blond-je* 'N, blond girl'; *speel* 'V, to play' - *speel-tje* 'N, toy.'

Note that this does not indicate that derivation must be category-changing. When we add the suffix *-er* to the noun *London*, we derive a word of the same nominal category. Yet, this is a clear case of derivation since *Londoner* and *London* are two different lexemes. They also belong to two different subcategories of nouns: whereas *London* is a proper name that cannot be preceded by a determiner (**the London*), Londoner is a count noun (*the Londoners*).

The evaluative morphology of some languages is a problem for this criterion. In Italian, for instance, evaluative suffixes create lexemes of the same lexical category as their inputs: *tavolo* 'N, table' – *tavolino* 'N, small table'; *giallo* 'A, yellow' – *giall-ino* 'A, yellowish' (Scalise, 1986). That is, this suffix is transparent to the lexical category of its inputs. Yet it looks like derivation because it creates new words with meanings that are distinct from those of the input words.

Inversely, there are forms of inflection that are not completely category-neutral. This applies, for instance, to the infinite forms of verbs such as participles and infinitives (Haspelmath, 1996). Infinitives, for instance, are forms of verbal lexemes. Yet they exhibit both verbal and nominal properties. They can combine with determiners and adjectives, which is typical of nouns. At the same time, they exhibit verbal properties such as co-occurrence with prepositionless nominal phrases, as in the following Dutch sentence:

(1) Het je moeder cadeautjes gev-en
the your mother presents give.INF
moet afgelopen zijn
should finished be
'You should stop giving presents to your mother'

Participles can function as pronominal adjectives while at the same time keeping their verbal properties, as illustrated by the following German example (Haspelmath, 1996: 44):

(2) der im Wald laut singende Wanderer
the in.the forest loud singing hiker
'the hiker who is singing loud in the forest'

The present participle *singend* is inflected as a prenominal adjective with the inflectional ending *-e*, whereas its co-occurrence with a locative adverbial *im Wald* and the adverbial *laut* indicates that it still has verbal valence as well. Thus, inflection may have effects on syntactic category. In contrast to the situation for derivation, in inflection the syntactic category of its inputs is preserved.

Paradigms

Inflection is typically associated with paradigms. A paradigm is an abstract pattern of cells, with each cell having a particular value for one or more inflectional categories such as number, case, tense, or aspect. For each lexeme of a particular lexical category, the cells of the paradigm are filled with particular word forms. This paradigmatic organization of the inflectional forms of a lexeme reflects the idea that inflection is obligatory in the sense discussed above. Of course, one may also organize the set of derivationally related lexemes into a paradigm. For instance, for English verbs one might assume a paradigmatic cell for 'agent noun.' However, there are many English verbs for which this cell might be hard or impossible to fill, as is the case for verbs such as *to die* and *to fall*. This stands in contrast with inflection where the cells of paradigms are (almost) always filled. An exception to this generalization is that nouns may lack plural forms, mainly for semantic reasons. In Russian, some verbs have defective paradigms, with one or more empty cells.

The notions of 'suppletion' and 'periphrasis' that are used in the analysis of inflectional systems also reflect the idea of obligatoriness and the idea of a paradigmatic organization of inflectional forms. For instance, if we say that *went* is the suppletive past tense form of *to go*, this presupposes that the past-tense cells of the verb *to go* must be filled by some word form. The same applies to *worse*, which is considered the suppletive comparative form of *bad*. On the other hand, there is no particular reason that we would want to consider *thief* as the suppletive agent noun of the verb *to steal*, instead of the derived noun *stealer*.

We speak of periphrasis if one or more cells of a paradigm cannot be filled by a particular word form. Instead, a combination of words must be used. For instance, in Latin there are no synthetic forms for the

passive perfect of verbs. Whereas the third-person singular present-passive form of the verb *laudare* 'to praise' is *laudatur* '(s)he is praised,' the perfect counterpart cannot be created by morphology and is expressed by a combination of a participle and a form of the word *esse* 'to be': *laudatus est* '(s)he has been praised.'

Related to the notion paradigm is the observation on inflection that many languages have different inflectional classes for the paradigms of lexemes. In Latin, for instance, there are five different declensional classes for nouns. This means that there are five different ways of computing the different word forms of the cells of a Latin noun. Many languages have different conjugations for the computation of verbal word forms. This illustrates that the relation between form and morphosyntactic information in the realm of inflection might be quite complicated. Another example of this complex relation between form and meaning in the domain of inflection is that more than one inflectional property is often expressed by one morpheme. In Indo-European languages, case and number are usually expressed by the same morpheme. The morpheme *-i* of Latin *hort-i* 'garden, GEN.SG' expresses both number and case. It is therefore a case of multiple exponence: two morphosyntactic properties are expressed by one and the same morpheme. The derivational morphology of Indo-European languages, on the other hand, is usually agglutinative, with each property being expressed by a separate morpheme. Thus, inflection and derivation may differ as to their formal morphological properties.

These distinguishing formal properties of inflection have led to formal models of inflection in which the paradigm plays a central role such as the Word-and-Paradigm Theory of Matthews (1972) and the realizational theories of inflectional morphology of Anderson (1992) and Stump (2001). In realizational theories, inflectional rules are seen as operations that spell out the phonological form of a lexeme for each combination of morphosyntactic features that may be assigned to that lexeme. That is, they indicate how a particular array of morphosyntactic features is realized. It is an open issue in present-day morphological theory to what extent the realizational model is an appropriate model for derivational morphology as well. In many ways, derivation is structurally similar to compounding, which suggests a primarily syntagmatic analysis of derived words, with affixes being concatenated to stems. For instance, there is a strong structural similarity between compounds and English derived words such as *help-ful* and *category-wise*, and the meaning of these words can be derived straightforwardly from those of their constituent morphemes.

Another characteristic of inflection is that inflectional paradigms may make use of more than one stem for computing the different forms of a lexeme. That is, there is formal variation without concomitant grammatical or semantic differences. The Latin verb *ponere* 'to put' has three different stem forms, *pone-*, *posu-*, and *posit-*, as in *pone-o* 'I put,' *posu-i* 'I have put,' and *posit-us* 'put, past participle.' This is no exclusive property of inflection: stem allomorphy also occurs in derivation, as illustrated by the English word pair *drama/dramatic*, where the adjective has been derived from a second stem form *dramat-* (Aronoff, 1994).

Semantic Differences

Is there any difference between the semantic categories expressed by inflection and those expressed by derivation? Inflection is used cross-linguistically for a number of categories:

- Nouns: number, gender, definiteness, case
- Verbs: valency, tense, aspect, mood, person, number, gender
- Adjectives: degree, number, gender, case, definiteness.

Derivation, on the other hand, is used for a much wider range of semantic categories. In this respect, derivation is closer to the lexical expression of meaning than inflection.

Bybee (1985) has proposed to interpret the semantic difference between inflection and derivation in terms of the notion 'semantic relevance'. "A meaning element is relevant to another meaning element if the semantic content of the first directly affects or modifies the semantic content of the second" (Bybee, 1985: 13). Bybee argued that there are two factors that determine whether a certain notion is expressed inflectionally or derivationally: relevance and generality. The less relevant a category is for the root, and the more general it is, the better it lends itself to inflectional expression. The inverse applies to derivation. For instance, the meaning element 'causative' is usually expressed by derivational means (if not by lexical means) because that meaning is very relevant to the meaning of the stem. On the other hand, an inflectional category, such as tense, is not so much of direct relevance to verbal stems, but locates the state of affairs expressed by a clause with respect to the time of speaking. Hence, tense does not modify the meaning of the verbal stem and has a deictic function instead. Correlating with this semantic distinction, we see that the morphological expression of tense in paradigms is quite general, whereas the morphological expression of causative may be possible for a

restricted number of verbal roots only. Inflection of the agreement type such as person-number marking on verbs and gender marking on adjectives and verbs has no obvious relevance to the meaning of the stem, and hence this kind of contextually determined morphology is the prototypical case of inflection.

According to Bybee (1985), this gradual semantic difference between derivation and the different kinds of inflection correlates with the order in which derivational and inflectional elements occur in a word: derivational elements are closer to the root than inflectional elements because they have a higher semantic relevance. In addition, the order of inflectional elements in an inflectional word form reflects different degrees of relevance. For instance, since the category of aspect is more relevant for the meaning of the stem than tense, tense morphemes tend to be peripheral to aspectual morphemes. Person and number markings on verbs (necessary for reasons of agreement only) are peripheral to tense marking.

Properties of Inflection and Derivation

Inflectional processes are said to be fully productive, whereas derivational processes may exhibit different degrees of productivity. This seems to be a natural corollary of the fact that inflection is obligatory. However, this is not completely true, since there might be competing inflectional processes with the same function, some of which may be unproductive. English plural nouns are created by the productive process of suffixation with one of the allomorphs of the suffix /z/, but there are also closed sets of nouns with a different plural forms, such as nouns of Greek origin in *-on*, as in *prolegomenon/prolegomena*. The past tense of English verbs is normally formed by adding *-ed* to the verbal stem, but there is also a set of verbs of which the past tense form is created by means of vowel change, as in *ride/rode*. Hence, inflectional rules can be unproductive.

Inflectional forms of lexemes are usually semantically regular, whereas derived words may exhibit all sorts of semantic idiosyncrasies. The derived word *baker*, for example, does not just denote 'one who bakes,' but is used to denote a certain profession. The de-verbal noun *dwelling*, as in *my humble dwelling*, does not denote the act of dwelling, but a location. Semantic idiosyncrasies in inflectional forms are much rarer, but do exist. For instance, the English plural form *brethren* is irregular, both formally and semantically, since it does not simply mean 'brothers,' but is used to denote male members of a religious community. In Dutch, the plural form of the noun *letter* 'letter,' *letteren*, is used to denote the scientific domain of arts and humanities.

A psycholinguistic difference that is sometimes claimed to correlate with the distinction between (regular) inflection and derivation is that between computation and storage. The idea is the following. Regular inflectional forms are processed on line: they are created by the speaker and parsed (decomposed) by the hearer. Hence, they may be assumed to be computed. Derived words, on the other hand, are stored as such in the mental lexicon and are retrieved as wholes from that lexicon in production and perception. This assumption concerns the differences in semantic regularity between inflection and derivation observed above; storage is often essential for assigning the right meaning to a derived word or for choosing the correct derived word, whereas regular inflectional word forms can be computed. Irregular inflectional forms, on the other hand, must be stored in the lexicon, for obvious reasons. For instance, the past tense form of *walk* is the regular, and hence predictable, form *walked*, whereas the past tense form of the verb *to fall*, the word form *fell*, is not predictable. This idea is referred to as the Dual Mechanism Theory of morphological processing (Pinker, 1999; Clahsen, 1999).

The Dual Mechanism Theory is based on the role of frequency in lexical decision tasks. In such tasks, subjects must decide whether a particular word (form) is correct. The frequency of occurrence of a word (form) may play a role in performing such tasks. The response latencies in lexical decision tasks correlate with frequency: a more frequent word will be recognized faster and will thus have shorter response latencies than a word of low frequency. This frequency effect is interpreted in terms of activation level. A word with a high frequency has a higher initial level of activation in the mental lexicon than a word with low frequency. Frequency effects presuppose the storage of the word (forms) involved. Hence, if there are no frequency effects for a particular word (form), one may conclude that it is not stored in lexical memory. Pinker (1999) and Clahsen (1999) argued, for English and German, respectively, that regular inflectional forms do not exhibit frequency effects, unlike irregular ones. This is explained by the assumption that only irregular inflectional forms are stored. According to Clahsen *et al.* (2003), derived words always show frequency effects, even the regular ones. Hence, derived words must be assumed to always be stored. Hence, the Dual Mechanism Theory should be restricted to the domain of inflection.

However, it has been shown in more recent psycholinguistic research that regular inflectional forms are also stored in the lexicon when they have a high frequency of occurrence (Stemberger and MacWhinney, 1988; Baayen *et al.*, 1997) since such regular forms also show frequency effects. In other words, the fact

that a correct inflectional form can be computed without lexical information does not necessarily indicate that the language user may not also make use of his or her vast lexical memory in the case of inflection and store and retrieve such complex forms.

A related psycholinguistic distinction between inflection and derivation is the family size effect (Baayen *et al.*, 1997). In the case of derivation, what counts in predicting differences in response latency between derived words is not so much the token frequency of the word forms for that word, but rather the number of morphologically related words (related in terms of derivational processes and compounding), that is, the size of its morphological family. The more family members a word has, the higher its initial level of activation in the mental lexicon.

Differences between inflection and derivation have also been found in studies of language users who suffer from certain forms of aphasia. For instance, Badecker and Caramazza (1989) investigated the language of an Italian aphatic and discovered that he made many inflectional errors, but almost no derivational ones. On the other hand, there are also speakers with agrammatism (aphatics with poor syntax and almost no function words) whose inflectional morphology is not affected and also preserved as their derivational morphology (De Bleser and Bayer, 1988). A survey of possible psycholinguistic differences between inflection and derivation can be found in Bertinetto (1995).

Morpheme Order and the Theory of Split Morphology

The functional differences between inflection and derivation and their formal correlates have led some linguists to propose the Theory of Split Morphology (Perlmutter, 1988; Anderson, 1992). In this theory, derivation is assumed to be accounted for by a pre-syntactic component of the grammar. This component generates derived lexemes in their stem forms, which are then inserted into syntactic structure as created by the syntactic component. Inflection, on the other hand, is accounted for in a post-syntactic component, because the choice of the correct inflectional form of a lexeme depends on the syntactic context in which it occurs. A consequence of this organization of the grammar is that inflectional elements will be peripheral to derivational elements, a prediction that is in accordance with Greenberg's Universal 28 mentioned above.

An earlier variant of Split Morphology is the theory of level ordering, as proposed for English by Kiparsky (1985). In this approach, all morphology is pre-syntactic. However, the set of morphological rules is ordered in two or more levels. Inflectional rules are located at the last level of the lexical component of the grammar and word formation at a preceding one. Hence, inflection is predicted to be peripheral to derivation. However, irregular inflectional forms such as the plural form *lice* of the noun *louse* may be formed at an earlier level, because in English, irregular plurals may occur within compounds, as in *lice-infested*. Although it may be true for English that only irregular plurals feed word formation, this restriction does not apply to related languages such as Dutch. For instance, Dutch has compounds such as *scholen-gemeenschap* 'lit. school-s community, comprehensive school' with the regular plural noun *scholen* 'schools' in first position. This compound contrasts with the Dutch compound *school-gemeenschap* 'school community,' with the singular or stem form of *school* in first position.

Therefore, the hypothesis of level ordering and, more generally, the hypothesis of Split Morphology are empirically inadequate as a general theory of how inflection and derivation interact, since it categorically excludes inflectional forms to form inputs for derivation, which is empirically incorrect (Booij, 1994, 1996). For instance, in many languages participles, which have both verbal and adjectival properties, can be used as stems for de-adjectival word formation, as in English *excitedness*, in which the past participle feeds derivation of nouns by means of the suffix *-ness*. In Dutch, the comparative forms of adjectives can be used as stems as well, as in the verb *ver-erg-er* 'to worsen' derived from the comparative form *erg-er* of the adjective *erg* 'bad'. Since comparative forms are usually classified as inflectional forms, this also forms a problem for the Split Morphology Hypothesis. It has also been observed that plural forms of nouns may function as stems in derivation. This is, for example, the case in Dutch, where the collective suffix *-dom* is added to plural nouns, as in *held-en-dom* 'heroism' with the morphological structure ROOT-PLURAL-COLLECTIVE. The root form is the noun *held* 'hero', which is followed by the regular plural suffix *-en*. Similar observations on Spanish and Portuguese can be found in Rainer (1996).

Compounding, another major type of word formation, also appears to use plural nouns as building blocks, as in Italian *lava-piatti* 'dish-washer,' a combination of the verbal stem *lava* 'to wash' and the plural noun *piatti* 'dishes.' Note that this compound has a singular meaning even though one of its constituents is plural.

Some linguists deny an absolute distinction between inflection and derivation and consider them to form one continuum (Bybee, 1985; Dressler, 1989). In this

view, interactions between derivation and inflection of the kind discussed above come as no surprise since it is the kind of inflection that is close to derivation that may feed derivation.

Although the Split Morphology Hypothesis faces certain problems, we must somehow account for the fact that derivation usually takes stems as their inputs, that is, words minus their inflectional elements. As pointed out above, that is the main formal reason for keeping inflection and derivation apart. In order to solve this paradoxical situation, we might distinguish between two types of inflection, inherent inflection and contextual inflection. An example of inherent inflection is the formation of plural nouns. In most contexts, the use of the plural form of a noun is not required by syntactic context, but a purely semantic choice based on what the language user wants to convey. The choice of specific finite forms of verbs, and of case forms of nouns, on the other hand, is governed mostly by syntactic context and then qualifies as contextual inflection. Participles and infinitives also qualify as cases of inherent inflection. The crucial observation is that it is only inherent inflection that can feed word formation processes such as derivation and compounding (Booij, 1994, 1996). This suggests that inherent inflection is halfway between derivation and contextual inflection. This is in line with the observation that inherent inflection may have class-changing effects, just like derivation, as observed above. In some psycholinguistic experiments, this distinction between inherent and contextual inflection is reflected by differences in frequency effects. For instance, Dutch verbal plurals are different from noun plurals as to frequency effects in lexical decision tasks. In certain tasks, verbs do not show a frequency effect, unlike nouns (Baayen *et al.*, 1997, 2003).

Yet, even inherent inflection cannot feed derivation, or more generally, word formation, on all occasions. For instance, the Dutch de-nominal suffix *-er*, which forms nouns, cannot be attached to plural nouns. The noun *wetenschapp-er* 'scientist' derived from the noun *wetenschap* 'science' is well formed, but we cannot add this suffix to the plural noun *wetenschapp-en* although this is an existing and well-formed plural noun of Dutch: **wetenschappen-er*. The crucial condition in the case of Dutch appears to be that inflectional elements must appear at the right edge of a prosodic word (Booij, 2002). Hence, plural suffix can appear word-internally before suffixes such as *-achtig* '-like' because the stem of such suffixes forms a prosodic word of its own, as in *boeken-achtig* 'books-like, bookish', which consists of the prosodic words (bukən) and (ɑxtəx). Therefore, the plural noun *boeken* 'books' can appear before the suffix *-achtig*.

In a number of languages, verbs may be preceded by so-called preverbs, which look like derivational prefixes. Classical examples of such word combinations are the particle verbs of Germanic languages. For instance, German *anrufen* 'to phone' looks like a word since it has a specific idiosyncratic meaning. However, the particle *an* can be separated from the verb in main clauses, as in *Johann ruft seine Mutter an* 'John calls his mother.' The past participle of *anrufen* is *an-ge-ruf-en*, with the inflectional prefix *ge-* before the root and after the particle. We might therefore think that this is a case in which a derivational prefix precedes an inflectional one, thus forming an exception to Greenberg's Universal 28. However, *anrufen* is not a word, but a lexicalized word combination, as is clear from the fact that it can be split in main clauses. Consequently, the position of the inflectional prefix *ge-* is as expected. Thus, if inflectional elements appear in between verbal stems and preverbs, this is no counterexample to the generalization that inflection tends to be peripheral with respect to derivation. Detailed studies of such preverb–verb combinations and their interaction with inflection can be found in Booij and van Marle (2003).

In sum, it is only in very specific circumstances that inflectional morphemes can appear inside derivational morphemes. Hence, Greenberg's Universal 28 remains an important generalization about the relation between inflection and derivation.

Influence of Literacy on Language Development

J Miller, University of Auckland, Auckland, New Zealand

What Is Literacy?

Literacy is a complex phenomenon with linguistic, social, educational, and political aspects. It includes the roles of written language in various social groups and settings, the structure of different types of text, and the tension between nonstandard and standard varieties. A central role belongs to the social capital residing in the mastery of complex written language. Every literate society obliges its children to spend many years subjected to rigorous formal education in which the teaching of complex written language is central. In spite of this, many literacy practices are at odds with practices found in formal education. The differences between spoken and written language bear directly on theories of first-language acquisition. In grammar and vocabulary, written language is far more complex than unplanned spoken language. Complex constructions are acquired after the age of seven and much later, and the study of literacy and written vs. spoken language does not support theories of rich innate linguistic knowledge.

One view of literacy is that it concerns how children learn to connect letters and sounds and that it is

primarily the business of those who teach younger children. Another interpretation is that literacy (literacies or literacy practices) has to do with the role of written language in a given society, especially how different groups use written language and the intertwining of written and spoken language in different situations. It also has to do with the organization of different types of text and how groups create their own text types rather than following the prescriptions of language arbiters (see Heath, 1983; Barton and Hamilton, 1998) This aspect of literacy leads to the issue of language, political power, and social capital (Collins and Blot, 2003) and the impact of literacy on the developing world.

In connection with first-language acquisition, all these aspects of literacy are important. Social capital is relevant because of the immense prestige of written language and because many children speak nonstandard varieties. Nonstandard varieties are not acceptable in the classroom and are not written; consequently, children who speak a nonstandard variety learn the standard. Because nonstandard and standard varieties of a given language can differ massively in syntax and vocabulary (see Miller, 2003; Kortmann, 2004), the task of learning written English is significantly more difficult for such children.

Children do not learn just the mechanics of syntax and vocabulary, centrally important though these are. They also have to learn to produce texts with the correct structure. Barton and Hamilton (1998) cited the case of the firefighter who was promoted to a senior position. One of his new duties was to take the minutes of meetings, but because he had been left to his own devices by the teachers and had left school at age 15, he had no training in advanced written English. He solved the problem by adapting previous minutes in the minute book, eventually becoming competent enough to write his own minutes. Heath (1983) discussed how those children in Trackton experienced in literacy practices lacking stories with the beginnings, middles, and ends that the school required; they were assessed as being less literate than children who did know the required story structure.

Literacy, Vocabulary, and Grammar

The rest of this article focuses on the vocabulary and syntactic structures that children have to control in order to master the written variety of their native language. An essential concept is magnasyntax, based on the term magnavocabulary introduced in Ong (1982: 103). Ong's idea was that an established written language acquires over the centuries a massive vocabulary, used in a large range of text types and recorded in dictionaries. Users can revive archaic words and analysts can reveal general patterns, but no user knows more than a small fraction of the magnavocabulary.

Formal text types contain a large number of lexical items that do not normally occur in unplanned speech; for instance, in English the set includes the extensive and much-prized Greco-Latinate vocabulary but also rare or archaic words from the Germanic core (not to mention the many borrowings from French and Italian having to do with literature and music). Children can learn this vocabulary only by private reading and formal teaching (and to some extent by having parents who use it). Eighteen-year-olds in their final year of secondary schooling typically have a respectable knowledge of literary English and technical terms from a number of subjects such as mathematics, physics, geography, and history, but tertiary education requires the intense learning of more vocabulary.

Magnasyntax

Established written languages are described in comprehensive grammars covering contemporary texts but also texts from previous centuries. Like magnavocabulary, magnasyntax is available to any user of English. For instance, conditions are typically expressed by conditional clauses in English: *if you forget your passport, you will be in trouble*. They can also be expressed in spoken English by imperatives: *forget your passport and you will be in trouble*. In very formal English, conditions can be expressed by yes-no interrogatives of the structure *was/were/should* + subject noun phrase, as in *should you require further information, telephone our office*. The construction is rare, marks texts as most formal and the writer as an expert user of written English, and belongs to magnasyntax.

Relative clauses illustrate magnasyntax rather well. Unplanned speech contains the sort of relative clauses in (1).

(1a) the applicant that got the job
(1b) the applicant that we preferred
(1c) the applicant we preferred
(1d) the applicant that I gave my vote to
(1e) the applicant I gave my vote to

The relative clauses are introduced either by the invariable conjunction *that* or by no conjunction; that is, they are contact clauses, as in (1c) and (1e). There is no pronoun in the relative clause referring back to *applicant*, just a gap: *the applicant that* [ ] *got the job*, *the applicant that we preferred* [ ] (where the boldface square brackets mark the gaps). The gaps are typically the subject or object, but are occasionally the

indirect object as in (1e). Prepositions come at the end of the clause.

More complex are *wh* relative clauses as in (2).

(2a) the applicant whom we preferred
(2b) the applicant to whom I gave my vote

The relative clauses in (2) are complex in that the *wh* pronoun is at the beginning of the clause, whether it is the subject or object, and the prepositions are also at the front of the clause, particularly in formal written English. Most complex of all are examples such as those in (3).

(3a) the hospital admitted several patients that month, for all of whom chemotherapy was the appropriate treatment
(3b) we read several government reports the gold lettering on the covers of which was admired by all the officials
(3c) he went to London, in which city he stayed for twenty years
(3d) she is not a person on whom to rely

The complexity lies in the *wh* pronoun's being part of a complex phrase, such as *for all of whom* in (3a) and *the gold lettering on the covers of which* in (3b); being the determiner of a noun, as in *in which city* in (3c); or being in an infinitival clause as in (3d), *on whom to rely*. These structures are absent from unplanned speech, but occur in formal writing.

Children learning to speak do not use structures missing from spontaneous spoken language. Perera (1984: 88–158, 223–247) gave an excellent overview, whose main points are reproduced here; her major finding is the number of constructions that are not mastered until age seven or much later.

- Only half of a set of 10-year-olds could accurately interpret the structure subject-verb-second object-direct object as in *we showed her the book*.
- Eleven-year-olds regularly use adverbs in verb phrases, as in *have been always trying*, but 6-year-olds rarely do.
- The sequence determiner-noun-prepositional phrase, as in *the toys in the box*, is rare between the ages of 5 and 12.
- Apart from set phrases such as *mum and dad*, coordinated noun phrases are not used extensively before age 5 and only become frequent between the ages of 8 and 13; the earliest coordinated noun phrases function as direct objects.
- The full passive appears late in children's speech; only 30% of a sample of 11-year-olds used a full passive, as in *the cup was broken by Susan*.
- Children under age 11 do not use finite or nonfinite clauses as the subject, as in *that the school team won made everyone happy* and *to see that film would be cool*.
- Thirty percent of a sample of 19-year-olds misunderstood free relative clauses after verbs such as *ask*, as in *ask Helen which book to read*.
- Children who use various adverbial clauses of time do not always understand the relationship between the main clause and adverbial clause.
- Only 40% of a sample of 9-year-olds used relative clauses in subject noun phrases.
- Primary school children generally do not use relative clauses introduced by *whom*, *whose,* or a preposition plus a relative pronoun, as in *the shop in which we bought it*.

Perera's observations accord with the examples of children's writing in Rosen and Rosen (1973: 137–138). One 7-year-old produced a coherent text with a beginning, middle, and end and correct syntax, but the syntax was simple, consisting of a contact complement clause, one adverbial clause of time, and one of reason but otherwise consisting of main clauses connected by *and*. The noun phrases were simple, apart from two that could have come from the teacher. An 11-year-old produced a text with more complex syntax, consisting of a complement clause, two adverbial clauses of time, two of condition, and two gerunds, *kept splitting the pieces up* and *by splitting the five and half inches in half*. The noun phrases were all simple.

Literacy, Magnasyntax, and Theories of First-Language Acquisition

Complex and Simple Syntax Many theorists of first-language acquisition argue that children are exposed to small quantities of data and to data of poor quality and are deprived of evidence as to which utterances are grammatically correct. Under these assumptions, the acquisition of the complex grammar of, say, English can only be explained by children's having a rich innate knowledge of constraints on syntactic structures. This knowledge is assumed to apply to all languages because children acquire whatever language is spoken by the community they are born into. (And many children acquire more than one language.) Detailed studies of unplanned speech, which is what children are mostly exposed to, raise the possibility that the assumption of rich innate knowledge is not necessary. Unplanned speech is distinguished by simple syntactic constructions, a restricted range of vocabulary, and the extensive use of fixed expressions and collocations. In contrast, theories that invoke rich innate knowledge are based on complex generative models of grammar designed

to handle the most complex constructions. These complex constructions occur not in unplanned speech but in written language. The latter is, arguably, learned rather than acquired and, as previously described, Perera demonstrated that many complex constructions central to the grammar of English are not used or understood even by teenagers. Because these constructions are considered to be part of adult competence, we cannot say that children acquire their first language by the time they reach the age of four. And because the structures typical of written language and learned between the ages of 4 and 11 or even later are rather numerous, we also cannot regard them as mere exceptions (see Pinker, 1994: 273.) Moreover, examples that are usually treated as belonging to a single construction should be treated as representing several constructions. Four-year-olds who use and understand *the picture I drew* do not necessarily use or understand *the book in which I found the poem* and should not be said to have acquired the relative clause construction; rather, they have acquired one of the many relative clause structures.

Degenerate Data A consideration of literacy casts doubts on other assumptions in various theories of first-language acquisition. For example, published written texts are not degenerate and not meager. They are carefully checked by copy editors, and material for children is edited with special care. A given text may not be elegant, but it will conform to the canons of standard written English, will have no hesitations or anacolutha, and will be coherent. Moreover, written texts are not evanescent; they stay on the page and they can be and are consulted again and again. Children read their favorite stories again and again and when very young they have their favorite stories read to them again and again (in houses where reading takes place, of course).

Explicit Instruction Children are encouraged to read at school. Difficult texts are explained, and they construct dictionaries containing new words. There is instruction and focused feedback, comments targeted at inappropriate syntax, vocabulary, or style. Teachers draw their attention to special constructions, encouraging students to combine clauses into the complex sentences that attract praise and to widen their vocabulary in the prized body of Greco-Latinate derivatives. Of course, such instruction may be resisted by students, especially when they are speakers of nonstandard varieties and are being advised to abandon their native variety and adopt the alien standard variety. Such resistance is also more frequent among teenage males than other groups.

Loss of Literacy

Heath (1983) made the important point that people who have a certain command of literacy when they leave school may lose that command. She observed that the workers at the Trackton mills never had the occasion to use written English; the mill management explained written documents to the workers and wrote down the workers' answers to questions, for example, on applications for loans. The workers who did not use written language at home quickly lost their literacy skills.

Written Language as Optional

According to Pinker (1994: 16), writing is an optional accessory and the real engine of verbal communication is the spoken language that we acquired as children. An alternative view is that literate users of a given language use many syntactic structures, a huge complex vocabulary, and much derivational morphology that they did not acquire as small children. Nor can language be considered no more of a cultural invention than upright posture and not as a cultural artifact that we learn in the same way we learn to tell the time (Pinker 1994: 18). In any language, the various genres and registers and their corresponding syntax and vocabulary are cultural artifacts that have been consciously developed and elaborated, and these conventional elaborations have to be learned by the children in a given society. Children may know the rules for writing fairy tales at an early age, but the rules for writing scientific papers, business reports, and legal documents are typically not learned before the age of 20.

Information Extraction, Automatic

H Cunningham, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction: Extraction and Retrieval

Information extraction (IE) is a technology based on analyzing natural language in order to extract snippets of information. The process takes texts (and sometimes speech) as input and produces fixed-format, unambiguous data as output. This data may be used directly for display to users, or may be stored in a database or spreadsheet for later analysis, or may be used for indexing purposes in information retrieval (IR) applications such as Internet search engines like Google.

IE is quite different from IR:

- an IR system finds relevant texts and presents them to the user;
- an IE application analyzes texts and presents only the specific information from them that the user is interested in.

For example, a user of an IR system wanting information on trade group formations in agricultural commodities markets would enter a list of relevant words and receive in return a set of documents (e.g., newspaper articles) that contain likely matches. Users would then read the documents and extract the requisite information themselves. They might then enter the information in a spreadsheet and produce a chart for a report or presentation. In contrast, an IE system would automatically populate the spreadsheet directly with the names of relevant companies and their groupings.

There are advantages and disadvantages with IE in comparison to IR. IE systems are more difficult and knowledge-intensive to build, and are to varying degrees tied to particular domains and scenarios. IE is more computationally intensive than IR. However, in applications where there are large text volumes IE is potentially much more efficient than IR because of the possibility of dramatically reducing the amount of time people spend reading texts. Also, where results need to be presented in several languages, the fixed-format, unambiguous nature of IE results makes this relatively straightforward in comparison with providing the full translation facilities needed for interpretation of multilingual texts found by IR.

The rest of this article:

- discusses the origins of IE and the parameters that condition its performance in application settings (see 'Language Computation without Understanding' below);
- presents some application scenarios in which IE is being deployed (see 'Application Scenarios' below);
- gives a canonical definition of five subtasks that collectively characterize the spectrum of IE systems (see 'Five Types of IE' below);
- looks at the development of IE research subsequent to the MUC (message understanding conferences) program of the late 20th century (see 'IE After MUC' below).

See also **Natural Language Processing: Overview**. Other overview sources on IE include: Cowie and Lehnert (1996); Appelt (1999); Cunningham (1999); Gaizauskas and Wilks (1998); Pazienza (2003).

Language Computation without Understanding

Information extraction in the sense discussed here grew out of work in the late 1980s and 1990s the Message Understanding Conferences (MUCs related to Grishman and Sundheim (1996); Sundheim (1995); Chinchor (1998) – *see* **Text Retrieval Conference and Message Understanding Conference**). (Previous work in computation with human language had attempted similar things in some cases, and indeed a related term "fact extraction" was in use as far back as the 1960s. A formal and widely accepted definition of IE did not emerge until the work discussed here, however.) These events were particularly distinctive because they employed a strict quantitative evaluation procedure where different research

In contrast, an IE system would automatically populate the spreadsheet directly with the names of relevant companies and their groupings.

There are advantages and disadvantages with IE in comparison to IR. IE systems are more difficult and knowledge-intensive to build, and are to varying degrees tied to particular domains and scenarios. IE is more computationally intensive than IR. However, in applications where there are large text volumes IE is potentially much more efficient than IR because of the possibility of dramatically reducing the amount of time people spend reading texts. Also, where results need to be presented in several languages, the fixed-format, unambiguous nature of IE results makes this relatively straightforward in comparison with providing the full translation facilities needed for interpretation of multilingual texts found by IR.

The rest of this article:

- discusses the origins of IE and the parameters that condition its performance in application settings (see 'Language Computation without Understanding' below);
- presents some application scenarios in which IE is being deployed (see 'Application Scenarios' below);
- gives a canonical definition of five subtasks that collectively characterize the spectrum of IE systems (see 'Five Types of IE' below);
- looks at the development of IE research subsequent to the MUC (message understanding conferences) program of the late 20th century (see 'IE After MUC' below).

See also **Natural Language Processing: Overview**. Other overview sources on IE include: Cowie and Lehnert (1996); Appelt (1999); Cunningham (1999); Gaizauskas and Wilks (1998); Pazienza (2003).

Language Computation without Understanding

Information extraction in the sense discussed here grew out of work in the late 1980s and 1990s the Message Understanding Conferences (MUCs related to Grishman and Sundheim (1996); Sundheim (1995); Chinchor (1998) – *see* **Text Retrieval Conference and Message Understanding Conference**). (Previous work in computation with human language had attempted similar things in some cases, and indeed a related term "fact extraction" was in use as far back as the 1960s. A formal and widely accepted definition of IE did not emerge until the work discussed here, however.) These events were particularly distinctive because they employed a strict quantitative evaluation procedure where different research

sites first defined a precise task, then implemented competing systems that were measured against human-annotated data in a controlled environment. Although this type of experimental procedure seems obvious in many other branches of science, its use prior to MUC was uncommon in many language processing contexts (perhaps due to the early association between the work and phenomenological fields such as linguistics, as opposed to empirical experimentation or engineering – Boguraev *et al.*, 1995). The experimental cycle of the MUC competitions drove progress in IE and led to the canonical definition that is presented below in 'Five Types of IE.' The series also contributed much of our understanding of how to measure the performance of IE systems (*see* **Natural Language Processing: System Evaluation**).

The MUCs were held over the decade from 1987; following this IE work took several directions, including commercialization of some of the basic techniques, additional work on portability (see 'Portable IE') and, most recently, connecting with efforts related to the general project of the Semantic Web Berners-Lee (1999) (see 'Ontology-Based IE' below).

An important outcome of the last 15 years of work on IE is that the community now understands reasonably precisely the various parameters that influence the performance of the technology in diverse application settings. (In other words, the scientific work has laid the basis for the engineering of practical systems.) The next section looks at these parameters.

Complexity vs. Specificity

The difference between the general project of language analysis (or understanding) and the more restricted enterprise of extraction is a response to the low performance of analysis in the general case. To illustrate, imagine that we wish to build an application which uses language analysis to support some of its functions. Then consider that items of information to be extracted can vary in complexity (e.g., we may be interested simply in people names or in complex events that involve multiple participants) and in specificity (e.g., we may be interested in general information reported in any way in any text or in specific domains reported in particular ways in certain types of text). If we plot the acceptable performance level of analysis components on a graph of complexity vs. specificity of the information to be extracted (Figure 1), then there is an obvious trade-off to be made between the two: the more complex the data to be extracted, the more specific must be the domain of discourse; the simpler the data, the more generally the extraction algorithms may be applied. This two-dimensional view of IE performance hides a number of subtle issues. Specificity of an IE task is in itself multidimensional, being influenced by both text type and genre. For example, a seminar announcement text (a very specific text type, easy for IE systems to analyze) may be harder or easier to process depending on genre. For example, if it is a seminar series about famous historical figures there may be ambiguity between the speakers' names and those of their subjects. Conversely, if the series relates to mobile telecommunications, the regularity and specificity of the terminology typical of this genre should make structural analysis easier. Therefore we must also consider the parameters text type and subject (or genre, or domain):

Figure 1 Performance trade-off relative to specificity and complexity.

- Text type: the kinds of texts we are working with, for example: *Wall Street Journal* articles, or email messages, or novels, or the output of a speech recognizer.
- Domain: the broad subject matter of those texts, for example: world events, or symptoms of a deficiency in a particular enzyme, seminar announcements, financial news, requests for technical support, or tourist information, and the style in which they are written, e.g., informal, formal.

Finally there is the question of the particular types of information that the IE user is interested in, for example: personal names, rocket launches, mergers between companies, problems experienced with a particular software package, or descriptions of how to locate parts of a city. We return to this issue in 'Five Types of IE' below.

Application Scenarios

This section contains some scenarios that illustrate how IE application software can mediate between the text and the structured information needs of various types of user. In each case, the user specifies an information need to IE development staff, who then prepare a custom extraction system. The input materials are increasingly defined as subsections of the World Wide Web, either the formal materials of news, company sites, etc., or the informal Web of weblogs, mailing lists and wikis. The IE developers must analyze the problem according to the dimensions outlined in 'Complexity vs. Specificity' above, and determine how to combine human and machine processing so as to attain the required performance profile (see 'Portable IE' below).

The types of scenario given here are of increasing relevance due in large part to the explosive growth, dynamic nature and multilingual content of the Web.

Financial Analysts

The Web contains various indications of how a company is viewed, and whether or not it can be expected to perform strongly in the coming period. Some of this data is already highly analyzed, e.g., financial news in English. Other data, in other languages, or from less well scrutinized sources, is both voluminous and obscure. IE can enable analysts to answer questions such as

- How many instances predicting strong performance for a particular company are out there?
- Over the past year how has the profile of predictions for this company changed?
- How many positive/negative sentiments were expressed for the company?

Marketing Strategists

The dynamic adjustment of marketing spending is currently made more difficult by the lack of metrics that indicate the impact of campaign elements. IE can support campaign tuning today based on yesterday's results, producing outputs such as:

> In this morning's IT press 7% of articles discussed your company. The average proportion of the article directly relating to your company was 33%. The figures for the other key players in your sector are summarized in the following table...

Similarly, we can measure the extent of media coverage relative to spend events:

> Company Y exhibited at Comdex. In the week following the exhibition 20% of the press that covered Comdex mentioned Y.

PR Workers

Public relations staff are concerned to identify negative reporting events as quickly as possible in order to respond. IE can be configured to report like this:

> The table below summarizes 12 negative reporting events concerning your company in the last 24 hours of IT news...

Media Analysts

IE can be used to create a range of media metrics, for example the media distance, or extent of collocational association, between concepts and products/companies:

> The media distance between your company and the subject of XML is 0.09; for IBM the value is 0.2.

Five Types of IE

By the time that it ended in 1998 (the final conference was MUC-7 (SAIC 1998)) the MUC programme had arrived at a definition of IE split into five tasks:

- Named entity recognition (NE)
  Finds and classifies names, places, etc.
- Coreference resolution (CO)
  Identifies identity relations between entities.
- Template element construction (TE)
  Adds descriptive information to NE results (using CO).
- Template relation construction (TR)
  Finds relations between TE entities.
- Scenario template production (ST)
  Fits TE and TR results into specified event scenarios.

In simpler terms, NE is about finding entities, CO about which entities and references (such as pronouns) refer to the same thing, TE about what attributes entities have, TR about what relationships between entities there are, and ST about events that the entities participate in. Consider these sentences:

> The shiny red rocket was fired on Tuesday. It is the brainchild of Dr. Big Head. Dr. Head is a staff scientist at We Build Rockets Inc.

NE discovers that the entities present are the *rocket*, *Tuesday*, *Dr Head* and *We Build Rockets Inc*. CO discovers that *it* refers to the rocket. TE discovers that the rocket is *shiny red* and that it is Head's *brainchild*. TR discovers that *Dr Head* works for *We Build Rockets Inc*. ST discovers that there was a rocket launching event in which the various entities were involved.

The scenarios presented above in 'Application Scenarios' deploy these five types of information invarious combinations (and with various typical performance profiles).

These various types of IE provide progressively higher-level information about texts. They are described in more detail below, with examples (see also the extended example in 'An Extended Example').

Named Entity Recognition

The simplest and most reliable IE technology is *Named entity recognition* (NE – *see* **Named Entity Extraction**). NE systems identify all the names of people, places, organizations, dates, amounts of money, etc. So, for example, if we run the text in Figure 2 (*The Independent*, London, 4th August 2004.) through an NE recognizer, the result is as in Figure 3. (The results shown here and below are from IE software distributed with the GATE system (Cunningham 2002) – *see* **Computational Language Systems: Architectures**.)

All things being equal, NE recognition can be performed at up to around 95% accuracy (see also 'Complexity vs. Specificity'). Given that human annotators do not perform to the 100% level (measured in MUC by interannotator comparisons), NE recognition can now be said to function at human performance levels, and applications of the technology are increasing rapidly as a result.

The process is weakly domain dependent, i.e., changing the subject matter of the texts being processed from financial news to other types of news would involve some changes to the system, and changing from news to scientific papers would involve quite large changes.

Figure 2 An example text.

Coreference Resolution

Coreference resolution (CO) involves identifying identity relations between entities in texts. These entities are both those identified by NE recognition and anaphoric references to those entities. For example, in

Alas, poor Yorick, I knew him Horatio.

coreference resolution would tie 'Yorick' with 'him' (and 'I' with Hamlet, if sufficient information was present in the surrounding text).

This process is less relevant to users than other IE tasks (i.e., whereas the other tasks produce output that is of obvious utility for the application user, this task is more relevant to the needs of the application developer). For text browsing purposes, we might use CO to highlight all occurrences of the same object or provide hypertext links between them. CO technology might also be used to make links between documents. The main significance of this task, however, is as a building block for TE and ST. CO enables the association of descriptive information scattered across texts with the entities to which it refers. To continue the hackneyed Shakespeare example, coreference resolution might allow TE or TR analysis to situate Yorick in Denmark. Figure 4 shows results for the example text from Figures 2 and 3.

CO breaks down into two subproblems: anaphoric resolution (e.g., 'I' with Hamlet); and proper-noun resolution. Proper-noun coreference identification finds occurrences of same object represented with different spelling or compounding, e.g., 'IBM,' 'IBM Europe,' 'International Business Machines Ltd.,' etc.). CO resolution is an imprecise process, particularly when applied to the solution of anaphoric reference. CO results vary widely; depending on domain perhaps only 50–60% may be relied upon. CO systems are domain-dependent.

Template Element Production

The TE task builds on NE recognition and coreference resolution, associating descriptive information with the entities. For example, from the Figure 2 text the system finds out that the 'Bush administration' is also referred to as 'government officials,' and adds this as an alias.

Template elements for the example text are given in Figure 5. The format is an arbitrary one; the point to note is that it is essentially a database record, and could just as well be formatted for SQL (structured query language) operations, or reading into a spreadsheet, or (with some extra processing) for multilingual presentation. See 'An Extended Example' for an example in a simplified format.

Good scores for TE systems are around 80% (on similar tasks humans can achieve results in the mid-90s, so there is some way to go). As in NE recognition,

Figure 3 Named entity recognition.

Figure 4 Coreference resolution highlighted in example text.

the production of TEs is weakly domain-dependent, i.e., changing the subject matter of the texts being processed from financial news to other types of news would involve some changes to the system, and changing from news to scientific papers would involve quite substantial changes.

Template Relation Production

Before MUC-7, relations between entities were part of the scenario-specific template outputs of IE evaluations. In order to capture more widely useful relations, MUC-7 introduced the TR task – see Figure 6. As described in Appelt (1999), "The template relation task requires the identification of a small number of possible relations between the template elements identified in the template element task. This might be, for example, an employee relationship between a person and a company, a family relationship between two persons, or a subsidiary relationship between two companies. Extraction of relations among entities is a central feature of almost any information extraction task, although the possibilities in real-world extraction tasks are endless." In general, good TR scores reach around 75%. TR is a weakly domain-dependent task.

Scenario Template Extraction

Scenario templates (STs) are the prototypical outputs of IE systems, being the original task for which the term was coined. They tie together TE entities and TR relations into event descriptions. For example, TE may have identified Isabelle, Dominique and Françoise as people entities present in the Robert edition of Napoleon's love letters. ST might then identify facts such as that Isabelle moved to Paris in August 1802 from Lyon to be nearer the little guy, that Dominique then burned down Isabelle's apartment building and that Françoise ran off with one of Gérard Depardieu's ancestors. A slightly more pertinent example is given in Figure 7, adapted from MUC-6 ARPA (1995).

ST is a difficult IE task; the best MUC systems score around 60%. The human score can be as low as around 80+%, which illustrates the complexity involved. These figures should be taken into account when considering appropriate applications of ST technology. Note, however, that it is possible to increase precision at the expense of recall: we can develop ST systems that do not make many mistakes, but that miss quite a lot of occurrences of relevant scenarios. Alternatively, we can push up recall

Figure 5 Template elements.

Figure 6 Template relations.

and miss less, but at the expense of making more mistakes.

The ST task is both domain-dependent and, by definition, tied to the scenarios of interest to the users. Note, however, that the results of NE, TR and TE feed into ST. Note also that in MUC-6 and MUC-7 the developers were given the specifications for the ST task only 1 month before the systems were scored. This was because it was noted that an IE system that required very lengthy revision to cope with new scenarios was of less worth than one that could meet new specifications relatively rapidly (see 'Portable IE'). As a result of this, the scores for ST in MUC-6/7 were probably slightly lower than they might have been with a longer development period. Experience from previous MUCs and from subsequent work suggests, however, that current technology has difficulty attaining scores much above 60% accuracy for this task.

An Extended Example

So far we have discussed IE from a general perspective. In this section we look at the capabilities that might be delivered as part of an application designed to support analysts tracking international drug dealing.

When the system is specified, our imaginary analyst states that "the operational domains that user interests are centered upon are ... drug enforcement, money laundering, organized crime, terrorism, legislation." The entities of interest within these domains are cited as "person, company, bank, financial entity, transportation means, locality, place, organization, time, telephone, narcotics, legislation, activity." A number of relations (or links) are also specified, for example between people, between people and companies, etc. These relations are not typed, i.e., the kind of relation involved is not specified. Some relations take the form of properties of entities – e.g., the location of a company – while others denote events – e.g., a person visiting a ship.

Working from this starting point, an IE system is designed that:

- is tailored to texts dealing with drug enforcement, money laundering, organized crime, terrorism, and legislation;
- recognizes entities in those texts and assigns them to one of a number of categories drawn from the set of entities of interest (person, company, etc.);
- associates certain types of descriptive information with these entities, e.g., the location of companies;
- identifies a set (relatively small to begin with) of events of interest by tying entities together into event relations.

For example, consider the following text:

Reuter – New York, Wednesday 12 July 2005.

New York police announced today the arrest of Frederick J. Thompson, head of Jay Street Imports Inc., on charges of drug smuggling. Thompson was taken from

Figure 7 Scenario template.

his Manhattan apartment in the early hours yesterday. His attorney, Robert Guliani, issued a statement denying any involvement with narcotics on the part of his client. "No way did Fred ever have dealings with dope," Guliani said.

A Jay Street spokesperson said the company had ceased trading as of today. The company, a medium-sized import-export concern established in 1989, had been the main contractor in several collaborative transport ventures involving Latin-American produce. Several associates of the firm moved yesterday to distance themselves from the scandal, including the midwestern transportation company Downing-Jones.

Thompson is understood to be accused of importing heroin into the United States.

From this IE might produce information such as the following (in some format to be determined according to user requirements, e.g., SQL statements addressing some database schema).

First, a list of entities and associated descriptive information. Relations of property type are made explicit. Each entity has an ID, e.g., ENTITY-2, which can be used for cross-referencing between entities and for describing events involving entities. Each also has a type, or category, e.g., company, person. Additionally, various type-specific information is available, e.g., for dates, a normalization giving the date in standard format.

Reuter
- id: ENTITY-1
- type: company
- business: news

New York
- id: ENTITY-2
- type: location
- subtype: city
- is_in: US

Wednesday 12 July 2005
- id: ENTITY-3
- type: date
- normalization: 12/07/2005

New York police
- id: ENTITY-4
- type: organization
- location: ENTITY-2

Frederick J. Thompson
- id: ENTITY-5
- type: person
- aliases: Thompson; Fred
- domicile: ENTITY-7
- profession: managing director
- employer: ENTITY-6

Jay Street Imports Inc.
- id: ENTITY-6
- type: organization
- aliases: Jay Street
- business: import-export

Manhattan
- id: ENTITY-7
- type: location
- subtype: city
- is_in: ENTITY-2

Robert Guliani
- id: ENTITY-8
- type: person
- aliases: Guliani

1989
- id: ENTITY-9
- type: date
- normalization: ?/?/1989

Latin-America
- id: ENTITY-10
- type: location
- subtype: country

Downing-Jones
- id: ENTITY-11
- type: organization
- business: transportation

heroin
- id: ENTITY-12
- type: drug
- class: A

United States
- id: ENTITY-13
- type: location
- subtype: country

(These results correspond to the combination of NE and TE tasks; if we removed all but the type slots we would be left with the NE data.)

Second, relations of event type, or scenarios:

narcotics-smuggling
- id: EVENT-1
- destination: ENTITY-13
- source: unknown
- perpetrators: ENTITY-5, ENTITY-6
- status: on-trial

joint-venture

id:	EVENT-2
type:	transport
companies:	ENTITY-6, ENTITY-11
status:	past

(These results correspond to the ST task.)

Multilingual Extraction

The results described above may be translated for presentation to the user or for storage in existing databases. In general, this task is much easier than translation of ordinary text, and is close to software localization, the process of making a program's messages and labels on menus and buttons multilingual. Localization involves storing lists of direct translations for known items. In our case these lists would store translations for words such as 'entity,' 'location,' 'date,' 'heroin.' We also need ways to display dates and numbers in local formats, but code libraries are available for this type of problem.

Problems can arise where arbitrary pieces of text are used in the entity description structures, for example the descriptor slot in MUC-6 TE objects. Here a noun phrase from the text is extracted, with whatever qualifiers, relative clauses, etc. happen to be there, so the language is completely unrestricted and would need a full translation mechanism.

IE After MUC

In this section we bring the story up-to-date by looking at developments in IE system portability, the ACE program which succeeded MUC, and the project of automated annotation for semantic web applications.

Portable IE

A particular IE application might be configured to process financial news articles from a particular news provider (written in the house style) and find information about mergers between companies and various other scenarios. The performance of the application would be predictable for only this conjunction of factors. If it was later required to extract facts from the love letters of Napoleon Bonaparte as published on wall posters in the 1871 Paris Commune, performance levels would no longer be predictable. Tailoring an IE system to new requirements is a task that varies in scale depending on the degree of variation in the parameters discussed in 'Complexity vs. Specificity.'

Therefore a central track of IE research addresses the issue of portability, and this has been one of the most fruitful areas of development since the end of the MUC program in the late 1990s.

We can distinguish three broad currents of work in this area:

1. Learning extraction rules of models from annotated examples.
2. Embedding learning systems within end-user systems.
3. Supporting the development of rules/models by skilled specialist staff.

The first approach is to learn part or all of the extraction system from annotated training data. The advantage is a reduction in the need for skilled staff to perform system porting. The disadvantages are:

- only simple data can be extracted, or complex data from simple texts, such as seminar announcements (in fact many of the algorithms currently common in this area were developed for screen scraping which is a simpler task than most language analysis). (Screen scraping is the process of deleting the presentational elements of data or text, e.g., as displayed on a web page, in order to allow further processing of the data. Sites that provide comparative shopping lists are often based on scraping the pages of competing suppliers and representing the data for comparison purposes.);
- large volumes of training data may be required.

Surveys of work in this area are to be found in Cardie (1997); Daelemans and Osborne (2003).

Secondly, researchers have attempted to embed learning within end-user tools where the users correct IE suggestions. This approach addresses the problem of the costs of producing training data associated with the learning approach by speeding up the annotation process. A cyclical method known as mixed-initiative learning is used, where the user begins by doing all the annotation work manually while the system learns in the background. When the quality of the learned models is high enough, the system can then propose annotations to the user; correction of mistakes is fed back into the learning algorithm. See Day *et al.*, (1997); Grishman (2001). Mixed initiative learning was reinvented as adaptive IE in later work.

Lastly, IE system portability can be maximized by providing a development environment for skilled staff to adapt a core system. The advantages are:

- the core system can be designed for robustness and portability;
- extraction data complexity is not limited by a learning algorithm;
- all the engineering aspects of the process can be taken care of by the infrastructure (from data visualization to performance evaluation).

The disadvantage is that the adaptation process is labor intensive, and it is difficult for end-users to acquire the necessary skills. A survey of work is available (Cunningham and Scott, 2004); *see* **Computational Language Systems: Architectures**.

ACE: Automatic Content Extraction

The automatic content extraction program (ACE, 2004; Maynard *et al.*, 2003) is a successor to MUC that has been running since a pilot study in 1999, which has continued the competitive quantitative evaluation cycles of its predecessor. ACE differs from MUC in three significant ways:

1. Several of the five MUC tasks defined in 'Five Types of IE' are conflated in ACE. The NE and CO tasks become a single entity detection and tracking (EDT) task in ACE, and the TE and TR tasks a single relation detection and tracking task. The ST task is renamed event detection and characterization.
2. The ACE tasks are more complex than their MUC counterparts in several ways. In the EDT task, for example, there is a more fine-grained taxonomy of entities, and it is necessary for systems to interpret metonymic entity mentions, requiring semantic analysis of the texts under consideration. Also, multiple domains and sources are used, including materials output from automatic speech transcription and optical character recognition programs.
3. The evaluation results from the ACE program are not public. Whereas in MUC all the competition results were made public, ACE results are restricted to the participants. The utility of the program for nonparticipants is therefore much lower than for MUC.

Ontology-Based IE

The Semantic Web aims to add a machine-tractable, re-purposeable layer of annotation relative to ontologies to complement the existing web of natural language hypertext (Fensel *et al.*, 2002; Davies *et al.*, 2002; Bechhofer *et al.*, 2003). In order to realize this vision, the creation of semantic annotation, the linking of web pages to ontologies, and the creation, evolution and interrelation of ontologies must become automatic or semiautomatic processes, and a significant body of recent work has looked at the application of ontology-based IE (OBIE) (Bontcheva, 2004) in this context. Figure 8 illustrates the way in which IE and other language technologies can be used to bring together the natural language upon which the current web is mainly based and the formal knowledge needed for a semantic web. Figure 9 illustrates OBIE in action: the ontology hierarchy appears on the right, with an annotated document in the center of the pane. OBIE poses two main challenges:

- the identification of concept instances from the ontology in the text;

Figure 8 Closing the language loop.

- the automatic population of ontologies with instances in the text.

Identification of instances from the ontology If the ontology in question is already populated with instances, the task of an OBIE system may be simply to identify instances from the ontology in the text. Similar methodologies can be used for this as for traditional IE systems, using an ontology rather than a flat gazetteer. For rule-based systems, this is relatively straightforward. For learning-based systems, however, this is more problematic because training data is required. Collecting such training data is, however, likely to be a bottleneck. Unlike traditional IE systems for which training data exist in domains like news texts in plentiful form, thanks to efforts from MUC, ACE and other program, there is a dearth of material currently available for Semantic Web applications. New training data need to be created manually or semiautomatically, which is a time-consuming and onerous task, although systems to aid such metadata creation are currently being developed.

Automatic ontology population In this case an OBIE application identifies instances in the text belonging to concepts in the ontology, and adds these instances to the ontology in the correct location. It is important to note that instances may appear in more than one location in the ontology, because of the multidimensional nature of many ontologies and/or ambiguity, which cannot or should not be resolved at this level.

Example systems The knowledge and information management system (KIM, Popov *et al.*, 2004) is an extendable platform for knowledge management which offers IE-based facilities for metadata creation, storage, and semantic-based search. It also includes a set of front-ends for online use that offer semantically enhanced browsing.

Magpie (Domingue *et al.*, 2004) is a browser add-in that uses IE to facilitate the interpretation of web-pages and collaborative sense-making. It annotates web pages with metadata in a fully automatic fashion and needs no manual intervention. It automatically populates an ontology from relevant web sources, and can be used with different ontologies. The principle behind it is that it uses an ontology to provide a very specific and personalized viewpoint of the web pages the user wishes to browse.

The SemTag system Dill *et al.* (2003) uses IE to perform large-scale semantic annotation with respect to the TAP ontology. It first performs a lookup phase annotating all possible mentions of instances from the TAP ontology. In the second, disambiguation phase,

Figure 9 Ontology-based IE in action.

SemTag uses a vector-space model to assign the correct ontological class or determine that this mention does not correspond to a class in TAP.

Information Structure in Spoken Discourse

T Kotschi, Institut für Romanische Philologie, Berlin, Germany

When producing spoken discourse, it is important for speakers, in order to transmit their message properly, to give it a structure that may support the appropriate understanding of the message on the part of the listener. This is normally done by marking some words or word groups as more important than others and by 'packaging' the message into units of different sizes. The listener, on the other hand, will perceive words or word groups as being more or less important and will detect different types of boundaries that will enable him or her to interpret the utterance on the basis of a division into units to be identified as paragraphs, subparagraphs, sentences, clauses, phrases, and others. The message as uttered by the speaker and interpreted by the listener will thus have a structure that can be characterized in terms of important information and of boundaries between units of different extension. This type of structure is commonly referred to as the information structure of a discourse.

Although the essence of these considerations seems to be uncontroversial, there are nevertheless divergent opinions on what may be considered to belong to information structure, and it is not always clear which categories should be used for the description of its different forms of manifestation. The reasons for this may be that the concept of 'important information' is interpreted differently, descriptions may be based on divergent theoretical assumptions, or either the sentence (or an equivalent linguistic expression) or the discourse may be in the focus of description. Regarding information structure in (spoken or written) discourse, research on its forms and functions is confronted with the problem that a discourse is a complex system of structural spheres within which information structure has to be assigned its theoretically and methodologically adequate place.

For the current purpose, it is assumed that some of the problems implied by the subject of this article may be adequately treated by referring to a global, modular approach to discourse analysis. Following an introduction to some frequently used basic concepts (topic, comment, active concept, semiactive concept, new concept, focus and presupposition), the central aspects of the subject are presented based on a distinction between elementary and complex organization forms in discourse, particularly between information structure and topical organization. Then, the phenomenon of 'punctuation,' which is an inextricable part of the subject under discussion, is discussed.

Basic Concepts

The concepts most frequently used in research work on information structure in discourse can be categorized into three different points of view.

Topic and Comment

First is the distinction between 'topic' and 'comment.' In using these terms allowance is made to the fact that in uttering a (minimal) discourse unit the speaker 'says something about something'; in other words, there is something that has to be regarded as the already established 'matter of current concern' about which new information is added. The added information is named 'comment,' whereas the information that has already been established and thus can serve as an anchoring point for the new information is designated as 'topic.' It is this 'aboutness' relation that connects the two categories. As Lambrecht (1994: 127) stated,

> A referent is interpreted as the topic of a proposition if in a given discourse the proposition is construed as being about this referent, i.e. as expressing information which is relevant to and which increases the addressee's knowledge of this referent.

In the discourse, *I saw John yesterday. He was angry*, the pronoun *he* in the second sentence refers to the topic (it is the 'topic expression'), whereas *was angry* designates the comment that is about this topic. A distinction has to be drawn between sentence topic and discourse topic. A sentence topic (*he* in the cited example) does not necessarily have to be congruent with the grammatical subject of the sentence in

When producing spoken discourse, it is important for speakers, in order to transmit their message properly, to give it a structure that may support the appropriate understanding of the message on the part of the listener. This is normally done by marking some words or word groups as more important than others and by 'packaging' the message into units of different sizes. The listener, on the other hand, will perceive words or word groups as being more or less important and will detect different types of boundaries that will enable him or her to interpret the utterance on the basis of a division into units to be identified as paragraphs, subparagraphs, sentences, clauses, phrases, and others. The message as uttered by the speaker and interpreted by the listener will thus have a structure that can be characterized in terms of important information and of boundaries between units of different extension. This type of structure is commonly referred to as the information structure of a discourse.

Although the essence of these considerations seems to be uncontroversial, there are nevertheless divergent opinions on what may be considered to belong to information structure, and it is not always clear which categories should be used for the description of its different forms of manifestation. The reasons for this may be that the concept of 'important information' is interpreted differently, descriptions may be based on divergent theoretical assumptions, or either the sentence (or an equivalent linguistic expression) or the discourse may be in the focus of description. Regarding information structure in (spoken or written) discourse, research on its forms and functions is confronted with the problem that a discourse is a complex system of structural spheres within which information structure has to be assigned its theoretically and methodologically adequate place.

For the current purpose, it is assumed that some of the problems implied by the subject of this article may be adequately treated by referring to a global, modular approach to discourse analysis. Following an introduction to some frequently used basic concepts (topic, comment, active concept, semiactive concept, new concept, focus and presupposition), the central aspects of the subject are presented based on a distinction between elementary and complex organization forms in discourse, particularly between information structure and topical organization. Then, the phenomenon of 'punctuation,' which is an inextricable part of the subject under discussion, is discussed.

Basic Concepts

The concepts most frequently used in research work on information structure in discourse can be categorized into three different points of view.

Topic and Comment

First is the distinction between 'topic' and 'comment.' In using these terms allowance is made to the fact that in uttering a (minimal) discourse unit the speaker 'says something about something'; in other words, there is something that has to be regarded as the already established 'matter of current concern' about which new information is added. The added information is named 'comment,' whereas the information that has already been established and thus can serve as an anchoring point for the new information is designated as 'topic.' It is this 'aboutness' relation that connects the two categories. As Lambrecht (1994: 127) stated,

> A referent is interpreted as the topic of a proposition if in a given discourse the proposition is construed as being about this referent, i.e. as expressing information which is relevant to and which increases the addressee's knowledge of this referent.

In the discourse, *I saw John yesterday. He was angry*, the pronoun *he* in the second sentence refers to the topic (it is the 'topic expression'), whereas *was angry* designates the comment that is about this topic. A distinction has to be drawn between sentence topic and discourse topic. A sentence topic (*he* in the cited example) does not necessarily have to be congruent with the grammatical subject of the sentence in

question. This may be illustrated by Lambrecht's example, *As for Rosa, John didn't really love her.* In this sentence, the pronoun *her* refers to the topic (which has been introduced by the phrase *As for Rosa*), and the open proposition *John didn't really love* designates the comment of this topic. As opposed to a sentence topic, a discourse topic is meant to be a referent that is pragmatically salient beyond the limit of a single sentence. There is a third category that has to be taken into account in connection with the topic–comment dichotomy. It is a discourse constituent that is apt to guarantee the spatiotemporal anchoring of the event being expressed and that has been called 'framework' by Chafe (1976).

The Status of Information

Another way of making relevant aspects of information structure explicit is to characterize 'information units' with respect to their 'referential status,' which is subject to various changes when discourse is produced and comprehended (Brown and Yule, 1983; Chafe, 1987; Prince, 1981). Three cases can be distinguished.

The first case concerns information units that are, at a given moment, already in the speaker's and the listener's mind (or are assumed by the speaker to be in the listener's mind); these are 'active' concepts (Chafe, 1987) that only have to be 'evoked' (Prince, 1981). For example, in the already cited discourse, *I saw John yesterday. He was angry*, the speaker, by using the noun phrase (NP) *John* in the first sentence, refers to an individual the corresponding concept of which hereafter is active and can be evoked by using the pronoun *he* in the second sentence. Also among the active information units are the speaker and the listener as well as objects or individuals that are contained in the speaker's and the hearer's sphere of attention. An active concept does not necessarily have to be congruent with a topic (although topics are mostly referents that correspond to active concepts); an example of an active information unit that is not a topic is *guy* in example (3).

Second, there are information units that are, in a certain sense, at the periphery of the speaker's and the listener's consciousness and are called 'semiactive' or 'accessible.' A concept may be accessible because it was active earlier or because it can be inferred from a concept (or a conglomeration of concepts, a scenario, or a schema) that was active earlier (or is still active).

The third type of information units groups those concepts that the speaker has to activate before or during the utterance of a given discourse unit (and/or that he or she assumes the listener will have to activate as well) because they were neither active nor semiactive earlier. These concepts are 'new' or 'brand-new' in the sense that they have been transferred from the inactive state to the active state. The cognitive cost of this procedure is in proportion to the 'newness' of the concept. Prince (1981: 236) allows for a further differentiation between brand-new entities that are 'anchored' and those that are 'unanchored.' "A discourse entity is anchored if the NP representing it is linked by means of another NP, or 'Anchor,' properly contained in it to some other discourse entity." In a discourse such as *I got on a bus yesterday and the driver was drunk*, the entity represented by *a bus* is unanchored, whereas in a discourse such as *A guy I work with says he knows your sister*, the NP *a guy I work with*, containing the NP *I*, represents an entity that is anchored because that entity is linked to the speaker. These two types of anchoring reflect degrees of identifiableness of a referent in a discourse (cf. also Lambrecht, 1994: 165).

The distinction between active, accessible, and new information units was first made in relation to the referential status of entities that are denoted by noun phrases. As discussed later, other entities, such as those that are represented by verb phrases and adjective phrases, can be treated analogously.

Focus and Presupposition

A third distinction of relevance is that between 'focus' and 'presupposition' (or 'focus frame'). Following a rather general characterization, it will be agreed that a focus marks some discourse unit by setting it off against a background (corresponding to the presupposition) in such a way that the relation to a set of possible alternatives is asserted. In this respect, what is emphasized is an aspect that would have to be located at the semantic level of sentence structure. On the other hand, as Lambrecht (1994: 52) stated, one has to admit that the distinction between focus and presupposition relates to the fact that a speaker, in making an assertion, always expresses a proposition that is "pragmatically structured" because it

> reflects not only a state of affairs but also the speaker's assumptions about the state of mind of the hearer at the time of utterance, by indicating what is assumed to be already given and what is assumed to be new.

In other words, a pragmatically structured proposition may contain a presupposition ("the set of propositions lexicogrammatically evoked in a sentence which the speaker assumes the hearer already knows or is ready to take for granted at the time the sentence is uttered") and an assertion ("the proposition expressed by a sentence which the hearer is expected to know or take for granted as a result of hearing the sentence uttered"). A focus, then, is "the semantic component of a pragmatically structured proposition

whereby the assertion differs from the presupposition" (Lambrecht, 1994: 213). For instance, if a question such as *Where did you go last night, to the movies or to the restaurant?* is followed by the answer *We went to the réstaurant* (where the acute accent shows the place of the main sentence accent), then *restaurant* marks the focus of the answer.

Information Structure and Topical Organization

In analyzing phenomena of information structure in spoken discourse, the interest of the linguist can be directed toward the structural properties of individual minimal discourse units and their linear concatenation, on the one hand, or toward more complex aspects of discourse structure, on the other hand. A theoretically and methodologically based distinction of these two perspectives is discussed in the global and modular approach to discourse analysis that has been elaborated by Roulet and collaborators (Filliettaz and Roulet, 2002; Roulet, 1997). In this approach, a distinction is made between modules and organization forms. Modules are the components of the model dealing with the elementary dimensions of discourse organization (i.e., syntax, lexicon, textual hierarchy, referential dimension, and interactional materiality). Organization forms can be elementary or complex. Elementary organization forms result from a combination of elementary dimensions, whereas complex organization forms result from what are called 'couplings' between elementary organization forms or between elementary dimensions and elementary organization forms. Regarding information structure, it is treated as something that is defined in an elementary organization form (called 'information structure'), on the one hand, and something that is defined in a complex organization form (called 'topical organization'), on the other hand.

Information Structure as an Elementary Organization Form

A piece of discourse is assumed to be a minimal discourse unit (or 'discourse act' or 'act') if it has reached a certain degree of completion, such that its content can be transferred into the 'discourse memory' (Roulet *et al.*, 2001). It may be difficult to decide whether, in a given case, the transferring procedure has actually been brought about. However, it is possible to rely on certain tests that may give rather clear indications of what would be an adequate decision. Thus, it will be clear that the unit in question is a minimal unit if it is possible to continue with a definite expression that anaphorically refers to a noun phrase of that unit (which would be the case, e.g., in *We invited Peter*$_i$ *in order to give the poor old man*$_i$ *another chance*; this sentence would then correspond to two discourse acts, the first one ending with *Peter*).

When the linear concatenation of discourse acts is taken into account, information structural articulation manifests itself primarily in the way in which 'thematic continuity' and the different modes of 'thematic progression' are organized.

Thematic continuity obtains in a structure being produced in two phases, such that a referent that shall be talked about is introduced as (part of) a comment in the first part of that structure before being used as a topic in its second part. Languages such as French dispose of special constructions, so-called 'presentational clefts' (cf. an example such as *il y a un camarade d'usine qui me ramène*, '(there is) a friend of mine from the factory (who) drives me back'), which can be used to fulfill the pragmatic maxim, "Do not introduce a referent and talk about it at the same time" (Lambrecht, 1987: 254).

Regarding thematic progression, three types have to be distinguished: progression with constant topic, linear progression, and progression by reference to a 'distant topic.' Cases of progression with constant topic are those in which the topic of a discourse act is identical to the topic of the preceding act or can be derived from it (e.g., on the basis of an associative anaphora or a part–whole relation). A topic is thus not obligatorily identical with an activated (or given) concept (in the sense discussed previously); it may be semiactive as well. In the case of linear progression, the topic of a discourse act follows from the comment of the preceding act. Topics of these two types can be referred to by a 'topic expression' (which in the case of the constant topic is normally a pronoun or an anaphorically used noun phrase), but they may also stay implicit. The following is a French example containing, in the third act, a constant topic that stays without topic expression (and is indicated between brackets) (from Roulet *et al*, 2001: 249):

(1) 1. *et cette histoire qu'on m'a racontée*
2. *qui est peut-être une légende*
3. (HISTOIRE) *que vous portiez toujours la même chemise pendant que vous écriviez un roman.*
1. 'and this story I heard of'
2. 'which is perhaps a legend'
3. 'that you always wore the same shirt when you were writing a novel'

The following example is a case of linear progression, where the topic of the second act (STARTED WALKING) remains unexpressed as well:

(2) *And they started walking. Toward these houses.*

Drawing a distinction between progression with constant topic and linear progression leads to the definition of a third type of thematic progression: The topic of a given discourse act has been introduced into the actual discourse by the utterance of an act that precedes several acts that come in between this act and the act in question, such that one might speak of 'progression by reference to a distant topic.' This type of thematic relation may play an important role in connection with the speaker's task of closing a larger chunk of discourse.

Topical Organization as a Complex Organization Form

The topical organization of discourse comes into view when information structure (as described in the previous section) is coupled with what is defined in some of the other modules of the global discourse organization. For instance, if information structure is coupled with the dimensions of syntax and the lexicon, one focuses on the linguistic means that can be used in different ways with respect to the choice of topic expressions or detachment constructions. Thus, in order to refer to a topic, a personal pronoun, a demonstrative pronoun or noun phrase, or a definite noun phrase may be chosen, depending on how the topic has to be searched for. (The use of a demonstrative pronoun, for example, presupposes that the topic referent can be found in the immediate context of the utterance.) Regarding detachment constructions, different types of detachment have been shown to be in relation with the previously mentioned forms of thematic progression: dislocation, hanging topic, '*thème détaché* c'est' (Stark, 1997), and others. (Thus, it has been observed that right dislocation can mark the particular saliency of a topic, whereas left dislocation, besides introducing a 'lexical support' for a pronominal topic expression, can fulfill various other functions, such as the function to simplify discourse processing or to trigger some special inference; cf. Lambrecht, 2001; Prince, 1997.)

Linking informational structure to the domain of 'knowledge about the world' (which is described in the module called 'referential dimension') may help to understand the processes by which changes in the status of discourse units are brought about. One can hypothesize that those processes are normally based on networks of conceptual representations that are activated in the development of verbal interactions. Thus, in example (1) cited previously, a mental concept STORY is activated by the utterance of *et cette histoire qu'on m'a racontée*. If one assumes that this implies the activation of other concepts, such as VERACITY and CONTENT, forming part of a conceptual network of which STORY is the central element, then it is possible to think that the speaker (and also the listener) of (1), at the moment of starting the third discourse act (*que vous portiez toujours* ...), will be able to use the conceptual relation between 'story' and 'content' in order to reconstruct the topic of this discourse act (cf. Roulet, 1998).

Finally, information structure can be linked to hierarchical structure. If this is done, the task of describing the processes underlying that type of thematic progression that has been labeled 'progression by reference to a distant topic' may be fulfilled in an adequate way. It will thus be seen that a constituent from a distant discourse act can be relatively well identified as the topic of an actually uttered discourse act if, for instance, the two acts are located at the same level of the hierarchical structure of discourse (which may be the case when the distance is created by a number of hierarchically subordinated acts coming in between).

Periodical Organization

Oral discourse shows an articulation that is determined by the conditions of its production. It is 'punctuated' in that it is partitioned into units the format of which is marked by prosodic features, syntactic constructions, and the use of certain discourse markers. In part, the interpretation of these units depends on how the information packaged in them has been structured. Punctuation of oral discourse is a phenomenon that, in the model of Roulet *et al.* (2001), is treated in a complex organization form called 'periodical organization' and that can be described by coupling information from the phono-prosodic and the information structure organization forms (among others). Among the phenomena of periodical organization that have raised particular interest are 'information flow' and the division of oral discourse into 'paragraphs.'

Information Flow

Spontaneous oral discourse is usually partitioned into relatively small units (cf. Chafe, 1987; Levelt, 1989). Normally, these units contain no more than five or six words. One is allowed to assume that the division of discourse into such units is determined by the manner in which speakers are treating the information they want to transfer. Out of large amounts of information, at subsequent points in their communicative activity, speakers will choose only those very small amounts of information that they can bring to the focus of their consciousness (or 'activate') at any one time. Information units that can be focused on correspond to concepts of objects, properties, and events – concepts that are typically expressed in

noun phrases, verb phrases, and adjective phrases. The number of information units that can be activated at the same time will be responsible for the extension of the segment of discourse with which these information units are referred to. Since the activation of information units affords time, it is plausible to assume that those segments of discourse are separated by pauses and other functionally equivalent means, such as discourse markers, repetitions of words, syntactic parallelisms, and, most important, a single, coherent intonation contour under which the segment can be subsumed (Kotschi, 1996a, 1996b). Segments that are separated by these formal markers are usually called 'intonation units.'

Intonation units normally contain more than one information unit. A typical distribution can be observed in the following example (cited in Chafe, 1987; the individual intonation units are indicated by numbers; the dots indicate brief breaks in timing (..) or full-fledged pauses (. . .); two hyphens indicate lengthening of the preceding segment; and the acute accent shows intonations peaks):

(3) (from a conversation about the importance for university teachers to have personal contact with their students)
1. . . . *It's fúnny though,*
2. . . . *I dó think that makes a díffference .. but,*
3. . . . *Í can recall . . .uh- - . . . a big undergraduate class that Í had*
4. . . . *where .. éverybody lóved the instrúctor,*
5. . . .*a - - nd .. he was a . . . real .. uh .. óld world . . .*
   Swíss– . . . guy,
6. *.. this was uh .. a biólogy course,*
7. . . . *a–nd he- - . . . left áll of the– sort of uh– . . . real cóntact with stúdents .. up to .. his assístants.*

Without counting discourse markers, hedges, epistemic attitudes, and the like, one can say that the sequence of this example contains the following information units (which have been separated by a plus): *it + 's funny + I + that + makes a difference + I can recall a big undergraduate class that I had + everybody + loved + the instructor + he + was a real old world Swiss + guy + this + was a biology + course + he + left all of the real contact with _ up to _ + students + his assistants*. The concepts corresponding to these information units can be in one of three activation states: active (or given), semiactive (or accessible), or inactive. A concept that has been active before has only to be evoked and therefore exacts only a minimal activation cost. When a concept is semiactive, it may be activated by deriving it from some other concept, and the activation cost will be somewhat higher. Finally, a concept that has to be transferred from an inactive state into an active state demands rather high activation cost. In (3), this is illustrated as follows: in line 1, *it* is in the state of an already active concept (which refers to what the speaker is about to say), whereas *'s funny* is a concept that the speaker has transferred from an inactive to an active state. In line 4, both *everybody* and *the instructor* refer to concepts that have been in a semiactive state (inasfar as they are accessible from the schema 'undergraduate class' that has been evoked in line 3). In addition to these, the information units *that*, *I can recall a big undergraduate class that I had*, *he*, *guy*, *this*, *course*, and *he* represent given concepts, *students* and *his assistants* refer to accessible concepts, and all the other information units stand for new concepts. The totality of the processes, by which semiactive and inactive concepts are transferred into active concepts (as well as those by which activated concepts may fall back into the state of semiactive concepts because they have not been evoked again for some time), is designated by the metaphor of 'flow' in Chafe (1994). Information flow may have important effects on such linguistic features as intonation, stress, word order, and pronominalization and is closely interrelated with thematic continuity and thematic progression.

Chafe hypothesizes that in spoken discourse, each intonation unit verbalizes one and only one new concept, and that in addition it may refer to one (or more than one) active concept and/or to one (or more than one) semiactive concept. For Chafe, the general restriction to one new concept per intonation unit is due to the cognitive work that the speaker has to perform in order to activate an inactive concept. The hypothesis concerning this 'one new idea constraint' can obviously be strengthened on the basis of data from other languages (cf. Kotschi, 1996a, 1996b), although it is still dependent on the somewhat optimistic assumption that the question of whether or not a linguistic expression corresponds to a single information unit can be answered satisfactorily in every single case.

Division into Paragraphs

From a slightly different perspective, consideration is given to the structure of discourse units that show a greater extension than do intonation units while still being identified and interpreted partly on the basis of prosodic features. Those units, especially the ones that sometimes are designated as 'paragraphs' (or 'mouvements périodiques'; Roulet *et al.*, 2001), may be characterized as manifesting a certain type of bipartite articulation, which shows a certain affinity with topic–comment articulation, without being identical to it. According to Morel and Danon-Boileau (1999), who studied spoken French discourse, paragraphs normally fall into two parts, a 'preamble'

and a 'discourse focus' (*rhème*) (which in special cases may be followed by a *postrhème*, i.e., a constituent that, showing an invariably low intonation contour, immediately follows the discourse focus; Blanche-Benveniste, 1997). Allowed by the possibility of recursive structuring, a paragraph can become the preamble of another, hierarchically superior paragraph.

In principle, the preamble will show considerable structural variety and can be much longer than the discourse focus. The latter, on the contrary, tends not only to be relatively short but also to not allow the same structural variety as the former. The discourse focus can be characterized as the constituent by which the speaker presents a piece of information that, without being necessarily 'new,' is likely to be subject to disagreement or discussion, whereas the preamble specifies the conditions in accordance to which the discourse focus may be adequately interpreted. The preamble can consist of up to five subconstituents, namely a 'connector' (which specifies the relation between the whole paragraph and some information in the discourse memory), an 'evidential expression' (*point de vue*) (allowing the listener to identify the source of the information to be given), a 'modal expression' (*modus dissocié*) (an item that may express an axiological judgment of the speaker or some epistemic modality), a 'frame' (specifying the domain for which the predication of the discourse focus is to be validated), and a 'detached lexical support' (which is a cover term for (parts of) constructions known as 'presentational cleft' (Lambrecht, 1987), '*thème détaché* c'est' (Stark, 1997), and 'left dislocation' (Prince, 1997)). Within the preamble, these five subparts can be well distinguished from one another and they appear in a fixed order. In uttering them, the speaker brings about something like an 'operation of decondensation.' This is in accordance with the fact that it is within the preamble where most of the hesitation phenomena, pauses, false starts, corrections, and other traces of 'formulation work' can be observed. Throughout the preamble, the process of formulation thus seems to be reflected and controlled by the speaker. In contrast, the utterance of the discourse focus seems to have been 'premeditated.' It shows a significantly lesser degree of formulation work, it is shorter than the preamble, and it is produced at a higher speech rate.

The following example illustrates a possible distribution of the elements that may occur in a paragraph:

(4) (from a conversation about linguistic norms)
mais moi je me souviens la première fois que j'ai reçu une lettre de ma marraine qui est quelqu'un que j'aime énormément c'était truffée de fautes
'as for me, I remember, when for the first time I received a letter from my godmother, someone whom I love very much, it was crammed with spelling errors'

In this case, the speaker has produced a relatively 'complete' sequence in which only the detached lexical support is lacking (Table 1).

In general, preambles in which all five positions are filled are rather exceptional. An actual constituent, however, may take over the function of a constituent that has been left unsaid:

(5) (from a conversation about cosmetic operations; Morel and Danon-Boileau, 1999)
et puis moi le risque c'est de ressortir avec des erreurs quoi
'and moreover, I would be afraid I might come out showing an inexactness'

The noun phrase *le risque* serves as support for the discourse focus and can, because of the semantics of its noun, also be understood as a modal expression (Table 2).

Table 1 Structure of a paragraph (Example 1)

Preamble					***Discourse focus***

Information Theory

M L Gregory, The State University of New York, Buffalo, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

'Information theory,' a term that arose sometime in the mid-1940s, refers to mathematical models of the amount of information in a message (Bar-Hillel, 1955). The desire of army intelligence and the telephony industry to find ways of transmitting a signal that did not deteriorate with distance or contain noise gave rise to the modern field of communication theory, including the notion of quantifying information. Claude Shannon (1916–2001) is credited with the innovations that led to the digital revolution. By equating truth values in Boolean logic to on-and-off electrical switches, Shannon showed how binary digits could be used in the analysis of switches and computer circuits. In his seminal paper, 'A mathematical theory of communication' (1948), Shannon demonstrated that language information could also be quantified as binary units. Working with a basic model of communication (a source message is transmitted over a noisy communication channel and is reconstructed at the destination), his major innovation was that all sources of information have a source rate and communication channels have a capacity rate, and these can be measured in the same units – binary digits, or bits. Information can be accurately transmitted over the channel if the source rate does not exceed the channel capacity.

'Information theory,' a term that arose sometime in the mid-1940s, refers to mathematical models of the amount of information in a message (Bar-Hillel, 1955). The desire of army intelligence and the telephony industry to find ways of transmitting a signal that did not deteriorate with distance or contain noise gave rise to the modern field of communication theory, including the notion of quantifying information. Claude Shannon (1916–2001) is credited with the innovations that led to the digital revolution. By equating truth values in Boolean logic to on-and-off electrical switches, Shannon showed how binary digits could be used in the analysis of switches and computer circuits. In his seminal paper, 'A mathematical theory of communication' (1948), Shannon demonstrated that language information could also be quantified as binary units. Working with a basic model of communication (a source message is transmitted over a noisy communication channel and is reconstructed at the destination), his major innovation was that all sources of information have a source rate and communication channels have a capacity rate, and these can be measured in the same units – binary digits, or bits. Information can be accurately transmitted over the channel if the source rate does not exceed the channel capacity.

The notion of quantifying information in bits has two fundamental principles. The first is that messages contain redundant information, and thus can be reduced to (or, more accurately, modeled by) a set of choices, the sum of which is less than the original message but still accurately represents the values of the original message. Consider, for example, sending a message in bits that contains one consonant, either a /t/, /d/, /p/, or /b/. Assuming that each consonant is equally likely, the message would contain 4 bits of information; the actual consonant in the message would be 'on,' and the others would be 'off':

(1)	t	d	p	b
	1	0	0	0

The fact that one bit is 'on' means that the other three are necessarily 'off,' which results in a lot of redundancy in the message. The redundancy can be reduced by using a representation of the data that reduces the number of choices encoded in the message, such as phonetic features:

(2)	**Voicing**	0 for voiceless, 1 for voiced	0	1
	Place	0 for bilabial, 1 for alveolar	0	1

In this model, it is necessary only to encode the values for two choices, reducing the average number of bits from 4 to 2.

The second principle of quantifying language information is the brilliant notion of Hartley (1928) that information is estimable via mathematical means. Following his suggestion that information can be quantified in logarithms, Shannon (1948) demonstrated that the amount of information in a source message is estimable by the logarithm of the number of available choices. The use of logarithms base 2 corresponds to binary digits, the same unit of measure used for channel capacity. Using Example (1), since the message, M, equals four equally likely values (consonants), $M = 4$, the information value of M, IM, is

$$IM = \log_2(4) = 2\text{bits}.$$

The information value of a message is a mathematical notion and should not be confused with any aspect of the meaning of the message. Shannon (1949: 3) made clear that the IM is distinct from the meaning of the message: "Frequently these messages have *meaning*; that is they refer to or are correlated with ... certain physical or conceptual entities. These semantic aspects of communication are irrelevant to the engineering problem."

Hartley's proposal of a mathematical model of information was based on the assumption that the possible values of a message were equi-probable. Shannon, on the other hand, showed that it is possible to exploit statistical knowledge about a source to reduce the estimate of the IM. His intuition was that distributional constraints, such as 'e' being expected when it follows 'th,' etc., reduce the redundancy of a message. Shannon (1949, 1951) employed *entropy*, a measure of the amount of information in a random variable (Manning and Schütze, 1999) to demonstrate that an unequal distribution of choices lowers the estimated IM. Entropy, H(x), denoted with an 'H' out of respect for Hartley (Devlin, 1999), is formalized as

$$\mathrm{H}(x) = -\sum p(x) \times \log p(x).$$

Shannon (1949) used letter frequency and context to compute the per-letter entropy of English as 2.3 bits. In 1951, he had participants predict letters in order to compute upper and lower bounds on their information value. He also demonstrated that increasing the number of letters in the context reduces the entropy (an upper bound of 1.3 bits for a context of 100).

Changing the assumptions of the consonant distribution in Example (1) illustrates how distributional constraints lower the estimated IM. Rather than assuming an equi-probable distribution, the following probability distribution is assumed: $p(\mathrm{t}) = 0.75$; $p(\mathrm{p}) = 0.15$; $p(\mathrm{d}) = 0.07$; $p(\mathrm{b}) = 0.03$. Thus,

$$\begin{aligned} H(x) = \quad & 0.75 \times -0.41504 &&= -0.31128 \\ & +0.15 \times -2.73697 &&= -0.41054 \\ & +0.07 \times -3.8365 &&= -0.26856 \\ & +0.03 \times -5.05889 &&= -0.15177 \\ & &&= \quad 1.114 \end{aligned}$$

The unequal distribution of the consonants reduces the average number of bits from 4 (for equi-probable choices) or 2 (when some redundancy is removed) to 1.114.

Shannon's formulization of entropy and further permutations of it (cf. Kolmogorov complexity, in Cover *et al.* (1989)) remain the core of information theory. Information theory is slowly expanding from an engineering tool to a modeling device in traditional areas of linguistics, such as phonology (Goldsmith, 2001; Bell *et al.*, 2003) and semantics (Resnik, 1999). However, the greatest contribution of information theory to linguistics is in computational linguistics, specifically statistical natural language processing. Although the field is too large to review here (see Charniak, 1993; Manning and Schütze, 1999; Jurafsky and

Martin, 2000), simply put, information theory (specifically, entropy and cross-entropy) is useful for evaluating how well a model fits the data. However, various instantiations of information theoretic principles have other important functions as well, such as measuring collocational strength (mutual information) or the difficulty of a search task (perplexity) (for a complete review, see Cover and Thomas (1991)).

Informative Analysis

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

Every speech act makes at least one illocutionary point. There is often more than one hearer, and the speaker may have different intentions toward (messages for) different hearers. All those who can reasonably consider themselves hearers are expected, as part of the cooperative endeavor, to keep tabs on what is said, so that if called on to participate in the discourse they may do so appropriately. Clark and Carlson (1982: 332) account for these facts through their 'informative analysis.'

> [T]he speaker performs two types of illocutionary act with each utterance. One is the traditional kind, such as an assertion, promise or apology; this is directed at the addressees. The other, called an informative, is directed at all participants in the conversation – the addressees and third parties alike. It is intended to inform all of them jointly of the assertion, promise, or apology being directed at the addressees.

Does every utterance in fact contain such an informative?

Suppose Sam utters (1) to H_1, H_2, and H_3.

(1) Will the last one of you to go to bed please turn out the light?

The informative analysis postulates the following illocutions:

(2) Sam **informs** H_1, H_2, and H_3 that Sam **requests** the last one of them to go to bed to please turn out the light.

The claim is that all hearers are informed of the request, but for the last one of them to go to bed (suppose it is H_2) the illocutionary point is that of a request – no request is made of H_1 or H_3. The traditional and simpler view is that the request is made of all three hearers because at the time of

Martin, 2000), simply put, information theory (specifically, entropy and cross-entropy) is useful for evaluating how well a model fits the data. However, various instantiations of information theoretic principles have other important functions as well, such as measuring collocational strength (mutual information) or the difficulty of a search task (perplexity) (for a complete review, see Cover and Thomas (1991)).

Informative Analysis

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

Every speech act makes at least one illocutionary point. There is often more than one hearer, and the speaker may have different intentions toward (messages for) different hearers. All those who can reasonably consider themselves hearers are expected, as part of the cooperative endeavor, to keep tabs on what is said, so that if called on to participate in the discourse they may do so appropriately. Clark and Carlson (1982: 332) account for these facts through their 'informative analysis.'

> [T]he speaker performs two types of illocutionary act with each utterance. One is the traditional kind, such as an assertion, promise or apology; this is directed at the addressees. The other, called an informative, is directed at all participants in the conversation – the addressees and third parties alike. It is intended to inform all of them jointly of the assertion, promise, or apology being directed at the addressees.

Does every utterance in fact contain such an informative?

Suppose Sam utters (1) to H_1, H_2, and H_3.

(1) Will the last one of you to go to bed please turn out the light?

The informative analysis postulates the following illocutions:

(2) Sam **informs** H_1, H_2, and H_3 that Sam **requests** the last one of them to go to bed to please turn out the light.

The claim is that all hearers are informed of the request, but for the last one of them to go to bed (suppose it is H_2) the illocutionary point is that of a request – no request is made of H_1 or H_3. The traditional and simpler view is that the request is made of all three hearers because at the time of

utterance it is unknown who will eventually comply with the request (perhaps none of them). This view is justified by a realistic true report of (1): Sam asked that the last one of us to go to bed should turn out the light. It would be unnatural to say Sam informed us that the last one of us to go to bed should turn out the light or for any of H_1, H_2, or H_3 to report Sam asked me to turn out the light; this is logically correct but pragmatically false because it ignores the true implicatures of (1).

(3) [Traffic cop addresses Ed in the presence of passenger Jo] Please show me your driver's license.
[Ed ignores the request, so the cop addresses Jo] You heard me ask him to show me his driver's license, didn't you?

It would not have been natural for the cop to say to Jo *I informed you that I asked him to show me his driver's license, didn't I?* (although he might say *I am asking this man to show me his driver's license*). In (3), the cop describes to Jo what she is doing and, indirectly, remakes the request of Ed. However, there is no confirmation of the informative analysis.

All entailments and implicatures of a proposition within the utterance are communicated, giving rise to indirect (and occasionally unintended) illocutions. Strictly speaking a speaker does not **tell** the hearer these things, but **lets them be known**.

(4) [Susan's mom to Susan's fiancé Fred in front of Susan] Why are you playing around with that Mabel?

Sentence (4) entails that Mom believes Fred is two-timing Susan. Her question directly challenges Fred to explain himself; but, if there has been no prior reference by any participant to Fred's affair, it also succeeds in indirectly (and tactlessly) informing Susan of the content of her mother's belief. This informative is not, however, sanctioned by the informative analysis, which requires that the challenge be inferred from the informative; in (4), the informative is inferred from the challenge.

Further examples can be brought against the informative analysis for proposing additional machinery to speech act analysis that serves no useful function (see Allan, 1986). The important point is that participants in a discourse keep tabs on what is said to whom and on everything that is implied in an utterance (Lewis, 1979). The informative analysis mistakes the communicative presumption (if an utterance appears to be linguistic, it is intended to communicate and is worth interpreting), cooperative expectations from participants, and the perlocutionary effects of utterances for the speaker's illocutionary intentions.

Ingarden, Roman (1893–1970)

M Hirschova, Olomouc, Czech Republic

© 2006 Elsevier Ltd. All rights reserved.

Roman Ingarden, born in Krakow, studied mathematics and philosophy (in Krakow, and then in Lvov with K. Twardowski), from 1912 to 1915 with E. Husserl in Göttingen. Later, he followed Husserl to Freiburg, where in 1917 he defended his dissertation *Intuition und Intellekt bei Henri Bresson.* After he obtained his Ph.D. in 1918, Ingarden returned to Poland for the rest of his life. First he was a grammar school teacher; after his habilitation thesis *Essentiale Fragen* was defended in 1925, he was appointed Associate Professor and, in 1933, full Professor at the Jan Kazimierz University in Lvov. During World War II (when universities were closed), he continued teaching in secret and worked on his major work, *The controversy over the existence of the world I, II* (published in Krakow in 1947 and 1948). After World War II, he moved to Jagellonian University in Krakow where he was offered a chairmanship. From 1949 until 1957, in the period of hard Stalinism, his academic career was interrupted by a ban from teaching

utterance it is unknown who will eventually comply with the request (perhaps none of them). This view is justified by a realistic true report of (1): Sam asked that the last one of us to go to bed should turn out the light. It would be unnatural to say Sam informed us that the last one of us to go to bed should turn out the light or for any of H_1, H_2, or H_3 to report Sam asked me to turn out the light; this is logically correct but pragmatically false because it ignores the true implicatures of (1).

(3) [Traffic cop addresses Ed in the presence of passenger Jo] Please show me your driver's license.
[Ed ignores the request, so the cop addresses Jo] You heard me ask him to show me his driver's license, didn't you?

It would not have been natural for the cop to say to Jo *I informed you that I asked him to show me his driver's license, didn't I?* (although he might say *I am asking this man to show me his driver's license*). In (3), the cop describes to Jo what she is doing and, indirectly, remakes the request of Ed. However, there is no confirmation of the informative analysis.

All entailments and implicatures of a proposition within the utterance are communicated, giving rise to indirect (and occasionally unintended) illocutions. Strictly speaking a speaker does not **tell** the hearer these things, but **lets them be known**.

(4) [Susan's mom to Susan's fiancé Fred in front of Susan] Why are you playing around with that Mabel?

Sentence (4) entails that Mom believes Fred is two-timing Susan. Her question directly challenges Fred to explain himself; but, if there has been no prior reference by any participant to Fred's affair, it also succeeds in indirectly (and tactlessly) informing Susan of the content of her mother's belief. This informative is not, however, sanctioned by the informative analysis, which requires that the challenge be inferred from the informative; in (4), the informative is inferred from the challenge.

Further examples can be brought against the informative analysis for proposing additional machinery to speech act analysis that serves no useful function (see Allan, 1986). The important point is that participants in a discourse keep tabs on what is said to whom and on everything that is implied in an utterance (Lewis, 1979). The informative analysis mistakes the communicative presumption (if an utterance appears to be linguistic, it is intended to communicate and is worth interpreting), cooperative expectations from participants, and the perlocutionary effects of utterances for the speaker's illocutionary intentions.

Ingarden, Roman (1893–1970)

M Hirschova, Olomouc, Czech Republic

© 2006 Elsevier Ltd. All rights reserved.

Roman Ingarden, born in Krakow, studied mathematics and philosophy (in Krakow, and then in Lvov with K. Twardowski), from 1912 to 1915 with E. Husserl in Göttingen. Later, he followed Husserl to Freiburg, where in 1917 he defended his dissertation *Intuition und Intellekt bei Henri Bresson.* After he obtained his Ph.D. in 1918, Ingarden returned to Poland for the rest of his life. First he was a grammar school teacher; after his habilitation thesis *Essentiale Fragen* was defended in 1925, he was appointed Associate Professor and, in 1933, full Professor at the Jan Kazimierz University in Lvov. During World War II (when universities were closed), he continued teaching in secret and worked on his major work, *The controversy over the existence of the world I, II* (published in Krakow in 1947 and 1948). After World War II, he moved to Jagellonian University in Krakow where he was offered a chairmanship. From 1949 until 1957, in the period of hard Stalinism, his academic career was interrupted by a ban from teaching

(for being an 'enemy of materialism'). Despite the difficulties of that period, he continued his work, and after being reappointed to his position in 1957, he soon published *The ontology of the work of art* (1962) and *Experience, artwork and value* (1969). He died suddenly in 1970.

Ingarden's best known works deal with aesthetics, especially literature, namely, with the ontological status of works of art of various kinds and with our means of cognizing them. His phenomenological approach to aesthetics strongly influenced the work of Michel Dufrennes. There are also strong resonances between Ingarden's work on the ontology of art and contemporary analytic works in aesthetics and in the development of the schools of New Criticism and Reader Response Theory (René Wellek and Wolfgang Iser, respectively).

In his *Literary work of art*, written around 1926 and first published in German in 1931, Ingarden attempted to determine the 'mode of existence' of a literary work, presenting compelling reasons to reject both attempts to identify literary works with 'real' objects or events, such as copies of texts or the psychological experience of authors or readers, and attempts to identify works of art with platonistic ideal objects, such as manifolds of sentences or sentence meanings.

As Ingarden ultimately argued, a literary work is a purely intentional formation, derived from the sentence-forming activities of its author(s) and founded on some public copy of these sentences. For its existence and essence, it also depends on a relation to certain ideal meanings attached to the words forming the text. Every literary work is composed of four strata: (1) Word sounds and phonetic formations of higher order (phrases, sentences, paragraphs); (2) Meaning units (from individual word meanings to meanings of phrases, sentences, paragraphs, etc.); (3) Schematized aspects (visual auditory or others, by the meanings of which the characters and places represented in the work may be apprehended); and (4) Represented entities (the objects, events, states of affairs, represented in the literary work and forming its characters, topics, etc.).

Each of the strata has its typical sorts of aesthetic value; thus, we may distinguish the values of rhythm, alliteration, interesting juxtapositions of ideas and concepts, and quasivisual beauty of the scene presented from the values of positive or negative characters and surprising plots. Nevertheless, those strata do not exist separately but rather form an organic unity. There are different forms of mutual dependence and influence among the strata that may contribute other aesthetic values and merits (or demerits) to the work. In cooperation with other strata, the stratum of represented objects may present metaphysical qualities such as the tragic, the dreadful, the peaceful, etc. The work of literature as a whole is a polyphonic harmony.

In 1928, Ingarden expanded his analyses of the ontology of art from literature to music, painting, and architecture in a series of essays published after World War II, as *The ontology of the work of art* (Ingarden *et al.*, 1989). In addition to those works, Ingarden also undertook a general work on the ontological status of the aesthetic object and on the nature of aesthetic values. Aesthetic values manifest themselves in the aesthetic objects created through concretizing the work of art and characterize the aesthetic object as a whole. Since various aesthetic objects may be based on one and the same work of art, these may also differ in their aesthetic values. This can help account for the variety of aesthetic judgments concerning the same work of art. Ingarden's goal is to account for the legitimate role of consciousness in constituting many of the objects and properties experienced by people, avoiding a pure subjectivism or universal social constructivism.

Inghen, Marsilius von (ca. 1335/40–1396)

D J Collins, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Marsilius of Inghen, Netherlandian scholastic and a master at the universities of Paris and Heidelberg, was an active participant in the 14th-century appropriation of Aristotelian logic into western philosophy and theology. A disciple of the Parisian nominalist John Buridan, he inclined toward the *via moderna*, but exhibited intellectual creativity and independence on numerous points. In the area of logic, Marsilius was a nominalist: individuals within a single species have no shared essence; however, the resemblance of such individuals is the basis for universal concepts, which exist solely in the human mind. In the area of natural philosophy, Marsilius argued that scientific knowledge must be based on sense data and self-evident propositions. For Marsilius, such a notion as the *creatio ex nihilo* cannot be derived without faith and thus does not belong to the legitimate propositions of natural philosophy. Nonetheless, Marsilius accepted that faith enjoys greater authority than reason and that in conflict reason must bow to faith inasmuch as the latter comes from God, who does not err. Delving into theology and epistemology, he argued that natural reason can form adequate concepts of and true propositions about God. Some indication of his enduring significance is to be noted in the use of the term *via marsiliana* in Germany after his death in reference to the *via moderna*, and in the oath stipulated in the 1427 statutes of the University of Louvain obliging doctoral candidates to foreswear teaching his doctrines, along with those of Buridan and Ockham.

The terms 'ingressive,' 'inceptive,' and 'inchoative' are all used to refer to the notion the beginning of an activity or state and to verbs, verb forms, and derivational processes connected to this notion. Sometimes, the terms are used indiscriminately, but there is a tendency to reserve 'inchoative' for the beginnings of states. In this article, 'ingressive' will be used as a cover term.

Ingressive meanings may be expressed in many ways in languages: by auxiliaries or auxiliary-like verbs, by derivational processes, or by inflectional means. In English, the productive way of expressing ingressivity is by verbs such as *begin* (taking verbs as its complement) or *become* (taking nominal elements or adjectives as its complement). In other languages, the same verb may show up with all word classes, e.g., Russian *stat'* 'begin, become' (originally a movement verb 'to stand up'). The English unproductive suffix *-en* as in *darken* is an example of a derivational ingressive (inchoative) that combines with adjectives. The Russian ingressive prefix *za-* combines with verbs as in *zapet'* 'begin to sing.' As regards inflectional forms, it does not appear to be common for such forms to have ingressivity as their primary meaning.

Sometimes, the terms are used indiscriminately, but there is a tendency to reserve 'inchoative' for the beginnings of states. In this article, 'ingressive' will be used as a cover term.

Ingressive meanings may be expressed in many ways in languages: by auxiliaries or auxiliary-like verbs, by derivational processes, or by inflectional means. In English, the productive way of expressing ingressivity is by verbs such as *begin* (taking verbs as its complement) or *become* (taking nominal elements or adjectives as its complement). In other languages, the same verb may show up with all word classes, e.g., Russian *stat'* 'begin, become' (originally a movement verb 'to stand up'). The English unproductive suffix *-en* as in *darken* is an example of a derivational ingressive (inchoative) that combines with adjectives. The Russian ingressive prefix *za-* combines with verbs as in *zapet'* 'begin to sing.' As regards inflectional forms, it does not appear to be common for such forms to have ingressivity as their primary meaning.

However, perfective forms of stative verbs may acquire an ingressive (inchoative) meaning, for example Greek aorist or French passé simple. In general, ambiguities between stative and ingressive readings are common, in particular with verbs such as English *realize* and *understand* or posture verbs in other languages.

Innate Ideas

E Margolis, Rice University, Houston, TX, USA
S Laurence, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

The question of whether there are any innate ideas or concepts goes back to ancient times and is at the center of the dispute between empiricists and nativists. Empiricists maintain that the mind has little innate structure and that all of our concepts are based on perception. In contrast, nativists maintain that the mind has a great deal of innate structure, including a stock of innate concepts of considerable abstraction (e.g., CAUSE, AGENT, NUMBER).

The traditional dispute between empiricists and nativists, especially in the 17th and 18th centuries, often confounded psychological issues with epistemological ones. While the former address how the mind is organized and how it develops, the latter address the grounds for justifying our beliefs. Contemporary theorists view the psychological issues as being largely independent of the epistemological issues. Contemporary theorists also draw upon empirical studies of the mind to support their claims. The cognitive sciences – from linguistics to developmental psychology to cognitive anthropology – all bear on the innateness controversy. At the same time, questions about innate concepts continue to be hotly debated among philosophers. One issue concerns what it means to say that a concept is innate and whether the notion of innateness has explanatory value. A second and related issue concerns which concepts (if any) are innate and how arguments for innate concepts are to be evaluated.

What Is Innateness?

Empiricists and nativists disagree about the innate structure of the mind. The disagreement is sometimes mischaracterized by saying that nativism is the view that the mind has an innate structure. This is a mistake, because the point of contention isn't about whether or not something is innate but is about how rich our innate endowment is. Even the most diehard empiricists maintain that the mind has an innate structure that is partly responsible for why humans develop the concepts they do. Even the behaviorist, as W. V. O. Quine notes, "is knowingly and cheerfully up to his neck in innate mechanisms" (1969, pp. 95–96). What distinguishes empiricists from nativists is that empiricists think that there are no innate concepts and that the innate mechanisms that explain how we acquire our concepts are general-purpose mechanisms (for empiricists the same mechanisms, ultimately based on our perceptual systems, are responsible for the development of such diverse concepts as NUMBER, BELIEF, SQUIRREL, and AXE). In contrast, nativists embrace innate concepts and allow that the mind may have considerable innate differentiation.

Some theorists are skeptical of the dispute between empiricists and nativisists because they think that little sense can be made of the idea that anything is innate. This poses a potential challenge (to both nativists and empiricists) to clarify the notion of innateness.

One proposal is that innate concepts are ones that are genetically determined. Unfortunately, the notion of genetic determination is itself problematic. Every phenotypic trait is dependent upon both genetic and environmental factors (including the embryonic environment); none can be traced to the genes uniquely. In addition, the appeal to genetic determination relies on a misleading picture that a genotype is a blueprint specifying a detailed sketch of an organism's phenotypic properties. But according to modern genetics, the relationship between genes and phenotypes is far more indirect (Sterelny and Griffiths, 1999; Marcus, 2004).

Another proposal is that innate concepts involve a greater influence of the genes than the environment in

However, perfective forms of stative verbs may acquire an ingressive (inchoative) meaning, for example Greek aorist or French passé simple. In general, ambiguities between stative and ingressive readings are common, in particular with verbs such as English *realize* and *understand* or posture verbs in other languages.

The question of whether there are any innate ideas or concepts goes back to ancient times and is at the center of the dispute between empiricists and nativists. Empiricists maintain that the mind has little innate structure and that all of our concepts are based on perception. In contrast, nativists maintain that the mind has a great deal of innate structure, including a stock of innate concepts of considerable abstraction (e.g., CAUSE, AGENT, NUMBER).

The traditional dispute between empiricists and nativists, especially in the 17th and 18th centuries, often confounded psychological issues with epistemological ones. While the former address how the mind is organized and how it develops, the latter address the grounds for justifying our beliefs. Contemporary theorists view the psychological issues as being largely independent of the epistemological issues. Contemporary theorists also draw upon empirical studies of the mind to support their claims. The cognitive sciences – from linguistics to developmental psychology to cognitive anthropology – all bear on the innateness controversy. At the same time, questions about innate concepts continue to be hotly debated among philosophers. One issue concerns what it means to say that a concept is innate and whether the notion of innateness has explanatory value. A second and related issue concerns which concepts (if any) are innate and how arguments for innate concepts are to be evaluated.

What Is Innateness?

Empiricists and nativists disagree about the innate structure of the mind. The disagreement is sometimes mischaracterized by saying that nativism is the view that the mind has an innate structure. This is a mistake, because the point of contention isn't about whether or not something is innate but is about how rich our innate endowment is. Even the most diehard empiricists maintain that the mind has an innate structure that is partly responsible for why humans develop the concepts they do. Even the behaviorist, as W. V. O. Quine notes, "is knowingly and cheerfully up to his neck in innate mechanisms" (1969, pp. 95–96). What distinguishes empiricists from nativists is that empiricists think that there are no innate concepts and that the innate mechanisms that explain how we acquire our concepts are general-purpose mechanisms (for empiricists the same mechanisms, ultimately based on our perceptual systems, are responsible for the development of such diverse concepts as NUMBER, BELIEF, SQUIRREL, and AXE). In contrast, nativists embrace innate concepts and allow that the mind may have considerable innate differentiation.

Some theorists are skeptical of the dispute between empiricists and nativisists because they think that little sense can be made of the idea that anything is innate. This poses a potential challenge (to both nativists and empiricists) to clarify the notion of innateness.

One proposal is that innate concepts are ones that are genetically determined. Unfortunately, the notion of genetic determination is itself problematic. Every phenotypic trait is dependent upon both genetic and environmental factors (including the embryonic environment); none can be traced to the genes uniquely. In addition, the appeal to genetic determination relies on a misleading picture that a genotype is a blueprint specifying a detailed sketch of an organism's phenotypic properties. But according to modern genetics, the relationship between genes and phenotypes is far more indirect (Sterelny and Griffiths, 1999; Marcus, 2004).

Another proposal is that innate concepts involve a greater influence of the genes than the environment in

the sense that innate concepts are bound to emerge in a wide range of environments (Sober, 1998). A related proposal is that a concept is innate to the extent that its development is canalized; that is, there is a developmental process that is bound to form the concept regardless of environmental variation (Ariew, 1996). One problem with these sorts of approaches is that some concepts are likely to emerge across a wide range of environments not because they are innate but simply because they are readily *learned* in a wide range of environments. A second problem is that for an account of this kind to work we must be given a principled specification of the relevant environmental variation (Cowie, 1999; Samuels, 2002).

Another approach is to explain innateness in terms of the kind of explanation that accounts for a concept. Samuels (2002) suggests that a psychological structure is innate when it is posited by a correct psychological theory and yet there isn't a psychological account of how it is acquired. For example, a concept is innate if we must turn to a neurobiological explanation of its acquisition. Of course, this leads to the problem of clarifying what counts as a psychological (as opposed to a nonpsychological) explanation, but perhaps this distinction is well enough understood in practice.

Which Concepts are Innate?

Much of the contemporary discussion about which concepts are innate has centered around Jerry Fodor's notorious claim that all **lexical concepts** are innate. Roughly, lexical concepts are ones that are encoded by single words in natural language, as opposed to phrases – for example, the concept DOG is a lexical concept.

Fodor's original presentation of his argument has the feel of a paradox (Fodor, 1975). The argument begins with the distinction between learning and other fortuitous ways of acquiring a concept (e.g., bumping your head in just the right way or undergoing futuristic neurosurgery). Fodor claimed that learning, in contrast with these other ways of acquiring a concept, should be understood as a rational process in which hypotheses are tested. The problem, as Fodor saw it, is that hypothesis testing requires that one already have the concept one is attempting to learn. He points out that in so-called concept learning experiments, subjects are required to sort stimuli in accordance with a novel concept. But if the correct hypothesis is, for example, that the concept in question is the concept of something that is blue or square, then one would have to have prior possession the concept BLUE OR SQUARE – the concept that is supposed to be learned – in order to even be in a position to frame and test the hypothesis. In later work, Fodor refined his argument by allowing that learning in some sense can take place so long as the acquired concept is complex. Learning is understood to be a process in which a new concept is constructed from previously available constituents in the course of framing and testing a hypothesis (Fodor, 1981). The problem now, however, is that the evidence is supposed to suggest that lexical concepts aren't complex, that they are actually atomic or primitive concepts (*see* **Concepts**). Fodor concluded that lexical concepts can't be learned, and hence that they must be innate.

The logic of Fodor's argument has been endorsed by such prominent cognitive scientists as Ray Jackendoff and Steven Pinker, who have agreed that concept learning can only be a process where complex concepts are assembled from their constituents (Jackendoff, 1989; Levin and Pinker, 1991). Where they have disagreed with Fodor is about the evidence regarding conceptual structure, maintaining that lexical concepts do in fact have the structure that would allow them to be learned. In contrast, philosophers have often simply dismissed Fodor's argument on the grounds that his strong form of nativism is inconsistent with evolution (Putnam, 1988). They point out that natural selection couldn't have given us an innate conceptual system that incorporates concepts of no utility to our ancestors (e.g., PROTON and SAXOPHONE).

Both of these reactions are unsatisfactory. The appeal to evolution barely addresses Fodor's argument. Simply dismissing his conclusion tells us nothing about where the argument goes wrong and gives us no insight whatsoever into how concepts can be learned. The strategy of localizing the disagreement to one about conceptual structure is certainly better. But it still embraces Fodor's fundamental assumption that there is no way of expanding the combinatorial expressive power of the conceptual system.

Another approach to Fodor's argument embraces the challenge of showing how a primitive concept can be learned (Margolis, 1998; Laurence and Margolis, 2002). The way to do this is to frame the issue of learning side by side with a theory of content that is suitable for primitive concepts, e.g., a causal theory of content. Roughly, on a causal theory of content, a concept's content is fixed by its standing in a nomic-causal relation with the property it expresses. These nomic relations aren't basic laws, so they must be supported by mechanisms that sustain the link between a concept and its corresponding property – sustaining mechanisms. Typical sustaining mechanisms involve inferential dispositions, but because of

the assumption of conceptual atomism, different people (and the same person at different times) can have different sustaining mechanisms for the same concept. What matters for the possession of a primitive concept is the property it is nomically connected to, not the mechanism that establishes the connection. The question of how a concept is acquired then becomes the question of how these sustaining mechanisms are established.

For natural kind concepts, one important type of sustaining mechanism may combine an appreciation of the typical appearance of a kind with a general disposition towards psychological essentialism (the view that instances of a natural kind have a common set of properties that bind them together and that account for the kind's appearance but are themselves not readily observable; see Gelman, 2003). If this is right, then acquiring a natural kind concept can be explained roughly as follows. Certain cues suggest that an object is an instance of natural kind; one is then disposed to keep track of its salient physical characteristics; and this information is organized around a new representation to interact with the general essentialist disposition. The result is a representation that is elicited by things with a similar appearance but that is withheld in those cases where the evidence suggests that the essential properties are missing.

It's natural to describe this whole process as one where a concept is learned, so it illustrates how a primitive concept **can** be learned. However, it doesn't follow that empiricism has been vindicated. Concept learning along these lines may depend upon innate cognitive mechanisms of considerable richness. For example, the model presupposes a disposition towards psychological essentialism and an ability to track natural kinds. These may very well be innate.

Moreover, nativist research has been flourishing in recent years with its focus on areas of cognition that are thought to be subserved by domain-specific systems. These are cases of distinct cognitive mechanisms that are differentiated in their developmental trajectory, that employ specialized computational operations, that draw upon a distinctive body of information, and that may be associated with specialized neural circuits. Some suggestions along these lines are a domain for reasoning about minds, a domain for reasoning about physical objects, a domain for reasoning about biological phenomena, and a domain for reasoning about social exchanges (Hirschfeld and Gelman, 1994; Carruthers *et al.*, 2005). Connected with these domains are strong candidates for innate concepts, including BELIEF, PHYSICAL OBJECT, ANIMAL, and CHEATER.

Debates over the existence and nature of innate knowledge have a long and complex history, in both philosophy and psychology in general and in language and linguistics in particular (see, e.g., Stich, 1975). As one might expect, such debates have produced many distinct and competing notions of innate knowledge and have also resulted in much disagreement over the existence of either necessary or contingent connections between any particular proposals (see, e.g., Griffiths, 2002). However, there are two senses of innate knowledge that consistently dominate both classical and contemporary work. First, that some set of 'ideas' or 'justified true beliefs' are present at birth, and, second, that there exists some set of domain-specific psychological mechanisms, capacities, faculties, or representations which are in some to-be-specified way biologically or genetically pre-determined.

Defense of innate knowledge in the first sense arguably began with Plato, who claimed that as we can be shown to possess 'genuine knowledge' for which experience is insufficient, then such knowledge must ultimately be something 'recollected' from what we already know. Philosophers of the Enlightenment also considered in detail the question of what kinds of knowledge may be innate, and in so doing questioned what the very notion of innate might mean. In direct contrast to Plato, John Locke (1690) argued that there are, in fact, "no innate principles in the mind" because, among other things, no useful meaning can be given to the notion of innate. Locke argued that if there were any innate principles, then either these principles must be present in our minds from birth, or there must be some 'mark' by which we can distinguish in adult minds those principles which are innate from those acquired by experience. But, Locke claimed, any supposedly innate principles are clearly not present in the minds of infants and 'idiots,' nor can the required marks be found. Thus, Locke concluded, no useful meaning can be given to the notion of innate in the context of explanations of the origins and development of human knowledge.

Note, however, that Locke's arguments here speak only to an understanding of innate knowledge in the first sense given above. Thus even if such arguments are correct, it remains entirely possible that there exists innate knowledge in the second specified sense. Moreover, there are now sound theoretical and empirical reasons to believe that innate knowledge in this second sense does actually exist (see Carruthers *et al.*, 2005, for a more detailed discussion of what follows).

Physiological traits such as teeth or pubic hair can be usefully understood as innate in this second sense, and there seems no reason to think that some psychological traits could not be similarly so understood. Furthermore, since the middle of the 20th century, results from research in linguistics and other areas of cognitive science, inspired by the pioneering work of Noam Chomsky (1965, 1967) appear to show that there exist various specific psychological traits which necessarily cannot be acquired via individual experience – as well as other traits which perhaps could be so acquired but which demonstrably are not. Thus there do indeed appear to exist some psychological traits that bear a 'mark' that distinguishes them from those that are experientially acquired. So much so, in fact, that for many core cognitive domains (e.g., language, naive physics, and number) virtually all contemporary researchers and theorists accept that there exists some degree of domain-specific innate knowledge – in the second sense – relevant to the domain in question. As Chomsky notes, all contemporary linguists agree that "the question is not whether innate structure is a prerequisite for learning, but rather what it is" (1980: 310), and it is with regard to the specific details of this innate structure that debate between linguistic nativists and non-nativists now occurs.

Evidence for an innate language faculty comes from a wide variety of theoretical and empirical sources, most of which are driven by what have been termed 'arguments from the poverty of the stimulus' (see, e.g., Chomsky, 1967, 1981; Laurence and Margolis, 2001; Pinker, 1994). These arguments claim to show, through a variety of different means, that the linguistic competence acquired by normally developing children cannot be – or demonstrably is not being – acquired using predominantly empiricist or general-purpose learning methods and mechanisms. Rather, nativists claim, these arguments show that there must exist a considerable amount of innate knowledge which enables children to bridge the 'gap' between the language-related input they receive, and their resultant linguistic abilities. Indeed, when one considers the way in which research in linguistics has proceeded in recent years, it rapidly becomes clear just how large this gap is, and thus just how much innate linguistic knowledge children must actually possess in order to bridge it. Contemporary linguists have discovered a huge number of subtle, but nonetheless fundamental, regularities in

our linguistic behavior and have put forward many different theories concerning the structure of language. Moreover, linguists have yet to comprehensively determine the grammar of even a single human language. This alone suggests that children's linguistic input is too impoverished to provide them with data sufficient to reach the one correct grammatical hypothesis, which they nonetheless reliably reach by the age of six years old.

In addition, there are theoretical decisions which the developing child needs to make – and reliably makes – but with which linguists have struggled for some considerable time. For example, are rules construction-specific or is sentence structure dictated by the interaction of a number of non-construction-specific rules? Are rules optional or mandatory? Do rules apply in a fixed order, or are they unordered? And so on. There is in fact a theoretically enormous range of grammatical hypotheses that the child could consider during language acquisition, but all normal children nonetheless always arrive at exactly the right hypothesis at approximately the same age. Moreover, all normal children also arrive at exactly the right hypothesis via pretty much the same route. If children were largely empiricist learners, one would expect that each child would try out a huge number of different grammars during language development, and also that the types of mistakes children would make would be highly variable. However, the sorts of errors children make are in fact highly circumscribed (Pinker, 1994; Crain and Pietroski, 2001). This (and much other) evidence therefore overwhelmingly supports the claim that there exists some degree of innate linguistic knowledge. The greater the amount and complexity of such innate knowledge one believes there is, the more nativist one is about our language abilities.

With regard to the actual content of our innate knowledge, many theorists (in linguistics and elsewhere) first draw a distinction between the information that cognition in any given domain requires, and the computational processes which operate on this information in that domain. More specifically, theorists often refer to representational modules and computational modules respectively (see, e.g., Fodor, 1983, 2000; Pinker, 1997; Samuels, 2000). The issue of what makes a cognitive capacity or faculty modular is complex and somewhat controversial (*see* **Modularity**), but to a first approximation, representational modules are domain-specific bodies of data (where this data is organized and integrated in the right kind of way), and computational modules are domain-specific processing devices. Thus, for instance, "a parser might be conceived of as a computational module that deploys the contents of a [representational] module devoted to linguistic information in order to generate syntactic and semantic representations of physical sentence forms" (Samuels, 2000: 19). Similar distinctions and consequent models can be generated in various other cognitive domains. Once these distinctions are made, however, it becomes clear that some components of either or both kinds of module could be innate in any given domain, and thus that specifying the details of our innate endowment will require considerable care. In addition, as our innate linguistic endowment will involve at least some extremely specialized representations and computations specific to human grammar, there is no reason to expect there to be any direct isomorphism between the details of our innate linguistic endowment and those of our innate endowment in other cognitive domains. Claims about the details of the innate knowledge appropriate to any given cognitive domain must therefore ultimately be made only in the light of the appropriate domain-specific investigation.

Furthermore, while it is clearly the case that not all language-specific representations or computational processes are innate (i.e., children clearly determine which representations and processes they should actually use on the basis of the input from their local environment), there is also no reason to believe that all the innate components required for language acquisition are language-specific. That is, successful language acquisition may also require the operation of innately specified but more domain-general processes, such as 'statistical samplers,' which can or do operate on any auditory or other input. However, the need for such domain-general processes does not detract from the claim that some innate language-specific components also exist. The linguistic capacities children acquire, and the routes by which these capacities are reached, admit of no other explanation.

This is not to say that linguistic nativists are all agreed on the details of our innate language-specific components. Mark Baker (2005), for example, points out that while it is clear that something like the Head Directionality Principle exists as part of our innate linguistic endowment, it is not yet clear whether this principle is innately specified as:

> 1. Combine a word with a phrase to make a larger phrase by putting the new word first *or* by putting the new word last.

Or as:

> 2. Form a new phrase by adding a word to a phrase.

More generally, there is still much disagreement between linguistic nativists over whether our innate

linguistic endowment is overspecified (as in 1) or underspecified (as in 2). Chomsky and many linguists who follow him currently argue broadly in favor of the former, whereas Steven Pinker, most 'functional' linguists, and most developmental psychologists argued broadly for the latter. Resolution of this debate will ultimately be an empirical matter, of course, but current theoretical arguments do not tell decisively either way. Nor is it clear how similar issues in other cognitive domains should either influence or be influenced by results from language acquisition. Thus despite the overwhelming nature of the theoretical arguments and empirical data outlined in the previous paragraphs in favor of linguistic (and other) nativism, there still exist some significant – though healthy – disagreements between even the most canonical nativists over exactly what the details of our innate endowment are. Nonetheless, such disagreements should not obscure the fact that, in the linguistic domain and elsewhere, our innate endowment is undeniably both rich and complex.

Finally, there is also the question of how our (neuro-)biology is able to implement or otherwise provide the innate knowledge which our linguistic and other cognitive abilities require. Given that aspects of our linguistic competence are not the product of our linguistic experience, it seems that these aspects must therefore be part of our biological endowment. This may strike one as somewhat counter-intuitive, but as Stephen Crain, Andrea Gualmini, and Paul Pietroski (2005) have recently argued "[o]ne cannot insist that our shared biology cannot give rise to knowledge of specific contingent linguistic facts if the available evidence suggests that our shared biology does just this." Moreover, it may turn out that the nature of these innate linguistic facts actually provides us with useful information about the manner in which human biology has evolved, given the evolutionary pressures and constraints which (proto-)language use will have imposed upon the primate lineage. Indeed, investigation into the interplay between our innate linguistic knowledge and the evolution of our species-typical biology, will undoubtedly be one of the more complex and fruitful areas for future research. The same is also likely to be true with regard our investigation into and our understanding of the innate knowledge involved in other cognitive domains.

In sum, then, in one important sense of 'innate knowledge' the existence of such knowledge in the context of linguistic and various other cognitive capacities is no longer in any serious doubt. However, much work is still required before our understanding of the specific nature of this knowledge will be complete.

Inoue, Kazuko (b. 1919)

F Katada, Waseda University, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Kazuko Inoue, among the first generative grammarians and a leading figure in the field of Japanese syntax, was born on April 17, 1919, in Osaka, Japan. She graduated from *Tsuda Eigaku Juku* (present Tsuda College, Tokyo) (1939). During her years as an English teacher in Osaka (1951–1963), she obtained opportunities to study in the United States, at Mills College (1951–1952) and at the University of Michigan (1957–1958; 1960–1961), where she received an M.A. in English linguistics (1958) and a Ph.D. in linguistics (1964). In 1963, she joined the faculty of the International Christian University, Tokyo, first as Lecturer (1963–1965), and then as Assistant Professor (1965–1967), Associate Professor (1967–1971), and Professor (1971–1985). In 1985, Inoue moved to Tsuda College and in 1988 to Kanda University of International Studies, where she became President of the University (1990–1997). She was President of the Linguistic Society of Japan (1983–1985). She was a member of various government councils including those of the Japanese Ministry of Education, Science, and Culture and the Japanese National Commission for UNESCO. She was the leader of the Center of Excellence project (1996–2001) at Kanda University, a large-scale research base funded by the government for the development of linguistics. Inoue is currently Professor Emeritus at Kanda University and is a member of the Science Council of Japan (since 2000).

Inoue's significant contribution to the field of generative grammar lies in her work on Japanese syntax. She was among the first to apply generative theory to a language other than English, namely, Japanese, and thereby advanced a research frame seeking linguistic universals across language boundaries. Her work in the late 1960s and 1970s anticipated the further development of generative syntax, from its early form with English as the focus of attention to a new orientation with principles and parameters in the 1980s, where examination of data from a wide range of languages received theoretical grounding. The introduction of linguistics as a science to the Far East owes much to her vital work, both her original work and her translations of some of the highly influential books in the field.

Linguist and social developer Inoue, born Japanese and female in the early 20th century, is an inspiring role model for young scholars, regardless of their gender, but for female scholars in particular since she is among the few women who have been recognized for their contributions to the professional world.

Insect Communication

K Reinhold, University of Bielefeld, Bielefeld, Germany
M Göpfert, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

Communication in insects has little in common with the elaborate use of language in humans. However, mainly because insects provide such a rich source of independently evolved communication systems, this group can hardly be ignored when describing the basic principles – causes, mechanisms, and consequences – of communication in nature.

To capture the essence of communication, various definitions have been proposed (Wilson, 1975; Bradbury and Vehrencamp, 1998). Nearly all authors agree that communication involves the transfer of information by a sender to a receiver, and that the vehicle that carries the information is the signal. Another integral point of most definitions is that the perception of the signal, and thus the received information, changes the behavior of the receiver. Here, we follow Wilson (1975) and subsume as communication those cases of information transfer that (a) change the behavior of the receiver in some way, (b) are adaptive or useful to one or both participants, and (c) involve intent on the communicator's part. The latter criterion is important, so as to exclude signals accidentally transmitted to the detriment of the sender, for example tracks or the rustling of mice in hay, which predators can use as cues to locate their prey. Such involuntary transmission of information is distinguished from communication in that it does not involve signals (Bradbury and Vehrencamp, 1998).

Probably due to the sheer number of insect species – roughly every second animal species is an insect – insects have evolved almost every conceivable way of communicating (Greenfield, 2002). Nearly every part of the body, from antennae through head, legs, wings, and body to genitalia, is used in some species for signal production or perception. Here we describe some of the various examples insects provide to explain the basic principles of communication.

One possible way to characterize the stunning diversity of communication in insects is by the physical modality and the sensory channel that are used for signal transmission. Insects communicate with visual, chemical, vibratory, and acoustic signals. All these forms of communication have independently evolved in many different groups of insects. Acoustic communication, for example, has evolved on numerous occasions in moths (Conner, 1999), grasshoppers and their allies (Greenfield, 2002), and many other insect groups (Yager, 1999). The four different channels for communication provide different advantages and disadvantages for communication. For example, different signals travel at different speeds. Visual signals travel at the speed of light (3×10^8 m/s). Acoustic signals travel at the speed of sound (in air 340 m/s). The spread of vibratory signals depends on the substrate and can be slower by about two and faster by about one order of magnitude compared to acoustic airborne signals. Finally, chemical signals propagate via diffusion or can be carried along with the wind (a few centimeters or meters per second). Because chemical signals are often by-products of metabolism, they can be comparatively cheap to produce. Depending on their physiochemical properties, they can have a long range, but they are often difficult to locate, they cannot transfer much information, and it takes time to switch them off. Visual signals can be switched on and off quickly, and in the absence of obstacles they have a medium range, but they are conspicuous for visually hunting predators. Vibratory signals have a very limited range but can transfer information to nearby receivers in a way that limits eavesdropping by predators. Acoustic communication, finally, has an intermediate to long range and also allows information to be transferred with signals that can quickly be altered. Most importantly, acoustic signals have the advantage that they can move around obstacles so that insects can communicate acoustically in dense vegetation, e.g., in meadows or forests. But producing them is often costly in terms of energy and eavesdropping by acoustically orienting predators can be a problem.

For several reasons, we concentrate our article on acoustic communication in insects as this signaling modality will be of most immediate relevance for those interested in language and linguistics. In addition, the general patterns of communication in insects can be well illustrated by examples of acoustic communication. And, due to space limitations, the article would lose more in depth compared to what it could gain in breadth when dealing with all signal modalities. The following section describes how acoustic signals are produced by the senders and detected by the receivers. A section thereafter then deals with the reasons why insects communicate, i.e., what benefits can accrue from communicating acoustically. In both sections, only a very small proportion of the huge number of sensory organs, sound-producing organs, and benefits of acoustic signaling can be mentioned. We have structured the second section around the advantages insects can gain from acoustic communication according to the receivers of the signals: potential predators, competitors, and mates. Theoretically,

signals could also be directed toward potential prey, but we are not aware of any acoustic signal that is used for this purpose. Visual signals, however, are occasionally used in this context: some firefly females (Lampyridae) attract their prey, heterospecific males, by mimicking prey-specific sexual signals, whereas some species of praying mantis (Mantidae) mimic flowers to attract their prey.

How Insects Produce and Detect Sound

Acoustic communication implies the ability to generate and detect sound. Insects have been remarkably innovative in this respect, with different insects having transformed different parts of their body into sound generators and detectors. The design of these generators and detectors, in turn, displays an almost bewildering diversity, representing multiple evolutionary solutions to how sounds can be detected and produced. This structural diversity is well reflected by the concert of distinct, mostly species-specific sounds insects are able to produce, which cover a frequency range of about 10 octaves and include barely audible hums as well as acoustic impacts louder than the noise of a concrete drill.

Sound can be generated when a vibrating structure sets the particles that make up the air into vibration, i.e., converts mechanical energy into acoustic. Specifically, the vibrations of the structure cause alternating compressions and rarefactions of the air, which propagate away from the vibrating structure at the speed of sound. This propagation is brought about by oscillations of air particles, which move back and forth from regions of high pressure to regions of low pressure, thereby turning low-pressure regions into high-pressure ones and vice versa. The two components, pressure and particle velocity, both contribute to the intensity of sound.

Flying insects inevitably generate sound by the movements of their wings. Though a mere by-product of locomotion, the faint, continuous sound produced by the wing-stroke is exploited by the males of some insects (e.g., mosquitoes, chironomid midges), which use it as an acoustic cue to detect and localize their females during flight (for a review, see Clements, 1999). Some insects additionally shake their wings to produce acoustic signals on purpose. Males of the fruit fly *Drosophila melanogaster* and some related drosophilid and tephritid flies generate courtship songs by fanning one of their wings while sitting on the ground (for a review, see Bennet-Clark and Ewing, 1977). With the wing-beat being decoupled from the requirements for flight, the sound can now be structured by moving the wings in specific temporal patterns, which allows the production of highly specific songs. This possibility has been exploited by the males of a number of drosophilid species, which produce courtship songs by rhythmically flipping their wings at distinct, species-specific intervals (Bennet-Clark and Ewing, 1977).

The sounds produced by moving the wings are usually restricted to frequencies below approximately 1 kHz, which is about the maximum rate at which the flight muscles drive the wing. A clever trick to overcome this frequency limitation is found in wax moths, which manage to produce high-pitched, ultrasonic sounds by moving their wings. The trick they employ resides in a tymbal mechanism. The moths have simply coupled their wing-bases to convex cuticular blisters (the tymbals) that buckle in and out like beer cans as soon as the wing is moved. Each buckling leads to a brief ultrasonic pulse of roughly 0.1 ms duration and very high sound frequencies of approximately 75–130 kHz (reviewed by Spangler, 1988). Hence, in wax moths, the activity of muscles no longer dictates the frequency of the sound, yet this mechanism still imposes a lower limit on the rate at which the sound pulses can be produced. Other insects have overcome the rate limitation imposed by muscular contractions. Much like wax moths, cicadas produce their prominent sounds by means of tymbals, yet their tymbals make use of an additional trick. In cicadas, the tymbals are not coupled to the wings but located laterally on the abdomen and are activated by abdominal muscles. Each tymbal comprises a series of ribs that buckle sequentially as the muscle contracts. The result is a fast burst of several sound pulses, with the intervals between the pulses of a burst no longer depending on the speed at which the muscles contract (for a detailed description of cicada sound production, see Young and Bennet-Clark, 1995).

An alternative, widespread method of producing fast sound bursts at various frequencies is stridulation. Here, structural vibration – and, hence, sound – is generated by rhythmically rubbing two body parts against each other, be it the two forewings (e.g., crickets, katydids), a leg and a wing (e.g., most grasshoppers, some noctuid moths), a leg or wing and the abdomen (e.g., certain grasshopper species), or scales on the genitalia and the abdomen (some sphingid moths) (for reviews, see Scoble, 1995; Ewing, 1989; Gerhard and Huber, 2002). Usually, one of the body parts involved in stridulation bears a sharp-edged cuticular scraper, whereas the cuticle of the other is toothed like a file. As the scraper moves across the file, the respective body appendages are set into vibration, resulting in the emission of sound. The courtship songs of grasshoppers well illustrate the complexity of the songs that can be produced that way (Helversen and Helversen, 1994). In these

insects, the hind leg bears a row of pegs (the file) that is rubbed along a protruding vein (the scraper) of the fore wing. Each time the scraper strikes a peg, a moderately damped acoustic impulse ensues. Subsequent impulses produced during one to-and-fro movement of the leg together form one syllable, with several syllables produced in series giving rise to a chirp. Grasshoppers repeat these chirps at stereotypic intervals, resulting in sequences that, reproduced at a regular rate, make up the complex songs these animals use to attract their mates.

The mechanisms insects employ to detect sound are about as complex as the ways by which their sounds are produced. Only things are – in principle – reversed: much as vibrating structures are used to generate sound, sound can be detected by measuring the vibrations of structures that move in response to sound. In effect, structures specialized to vibrate in response to sound and mechanosensory cells specialized to measure vibrations are the two principal components that make up an insect ear. The latter, the mechanosensory cells that mediate hearing in insects, are specialized neurons that are embedded into multicellular stretch receptors, known as chordotonal sensilla (for a review, see Field and Matheson, 1998). Spanning different regions of cuticle, these sensilla monitor relative movements of different body parts. Besides this proprioceptive function, a chordotonal sensillum can be employed for hearing if one of the cuticular regions it connects to vibrates sufficiently in response to sound to mechanically activate the sensillum. This sound receiver can take different shapes, depending on the parameter of sound to which it mechanically responds. Particle velocity receivers are light structures that directly follow the movements of the air particles in the sound field. Pressure receivers, in turn, are thin membranes that, spanning an air sac, are mechanically displaced by the pressure oscillations in the sound field.

Examples of particle velocity receivers are found in mosquitoes and drosophilid flies such as the fruit fly *Drosophila melanogaster*, which all rely on the particle velocity component to detect the faint, low-frequency sounds produced by the wing-stroke of conspecifics. In all these insects, hearing is mediated by the antennae, whereby the distal, third segment of each antenna constitutes the sound receiver. This receiver is proximally suspended by an antennal joint and, in addition, by the auditory chordotonal sensilla housed in the antenna's second segment, with the neurons comprised by the sensilla transducing the receiver's vibrations into electrical responses. Louder, high-pitched sounds as produced by tymbal mechanisms and stridulation are usually detected via ears endowed with pressure-receiving tympanal membranes (tympanal ears), which are formed by implementing tympanal membranes in various parts of the insect body, including the mouth parts (choerocampine hawkmoths), the neck (some parasitoid flies), the thorax or its appendages (e.g., noctuid moths, praying mantids, katydids, lacewings), and the abdomen (e.g., wax moths and other pyralids, geometrid moths, cicadas, grasshoppers, locusts, tiger beetles) (for reviews, see Scoble, 1995; Ewing, 1989; Yager, 1999; Gerhard and Huber, 2002). In most of these cases, the auditory chordotonal sensilla mechanically couple to the internal surface of the tympanum and are mechanically activated when the tympanum moves in response to sound.

While translating acoustic signals into electrical responses, hearing organs preprocess the information forwarded to the central nervous system. This preprocessing can involve highly sophisticated mechanisms such as the amplification of the ear's mechanical input by means of active movements of neurons, the amplification of directional cues by the acoustic or mechanical coupling of two ears, and the spectral analysis of incoming sound by mechanically channeling distinct frequency components to distinct populations of neurons, similar to what is known from vertebrate ears (e.g., Robert and Göpfert, 2002; Gerhard and Huber, 2002).

Why Insects Produce Sound

Acoustic communication can have different functions. One potential way to classify the bewildering variability of functions is to categorize them according to the receiver to which the produced sound is directed. Having in mind the three main problems an individual has to solve, (1) to survive, (2) to collect resources, and (3) to reproduce, the most important receivers are potential predators, competitors, and mates. The following paragraphs will describe some selected examples for each of these three groups.

For insects, as well as for other animals, communication with potential predators can increase the sender's chances of survival. Concerning the production of acoustic signals there is a clear parallel to visual signals that decrease predation risk. In some insects, acoustic signals are produced to show that the sender is unpalatable, the acoustic version of the visual combination of red and black, or black and yellow stripes. Such acoustic mimicry can be found in some tiger moths (Arctiidae), which signal their unpalatability with acoustic signals directed to hunting bats. However, detection of predators usually causes a cessation of sound production, a function similar to camouflage, which is widespread in insects. Other sounds

that are probably also directed towards predators are disturbance sounds, which various insects emit when grabbed by a predator or molested by an entomologist. These sounds, which include hissing, buzzing, or creaking, are not well examined, but may mimic snakes, bees, wasps, or the sounds that occur when a predator such as a bird bites on a twig. In all these cases, the insects have a chance to survive the initial attack if the predator is frightened or no longer interested in the seemingly unrewarding object. Even in those cases where signals are not directed towards predators, predators can have a large influence on the evolution of signals. Especially where predators or parasites can use acoustic signals to locate prey, some characteristics of the produced signals might be selected to decrease prey detection or location by the predators. In various groups of insects alterations in signal traits, or the evolutionary loss of signal production, have been attributed to selection by predators in line with these arguments (Greenfield, 2002). Notably, another crucial role for predators in the evolution of acoustic communication is certainly that selection by predators has been the most important driving force behind the evolution of ears. Since the evolution of acoustic signaling is unlikely to occur without the previous existence of hearing organs, noninsect predators and especially echo-locating bats may have played an eminent initial role for the evolution of insect acoustic communication.

A second important aspect is communication with potential competitors. As birdsong probably serves two different functions – courtship towards females and demonstration of strength towards competitors – acoustic signals in insects are likely to serve a dual function as well. In many insect species where the signals are generated only by males, the males are not randomly distributed across the available space. Usually, their nearest neighborhood distance is larger than expected from random spacing, and males are more regularly spaced than females. Apparently, the signaling males avoid each other, thereby reducing interference between their signals. Interestingly, in some species there are males that stay close to other, signaling males, yet these males refrain from signaling themselves. Such satellite behavior is known for crickets, where the silent, satellite males are choosy, preferring to gather with other males that are especially attractive to females. However, satellite behavior and spacing are not the only possible outcomes of acoustic competition. Males might, for example, try to increase their attractiveness to females in the presence of competitors. Signaling rate and amplitude have been shown to increase in some insect species and other signaling traits might also be changed by the presence of potential competitors. Competition might also lead to temporal coordination of acoustic signaling (Greenfield, 1994). In some species such coordination leads to alternation of acoustic signals so that males signal within the pauses of their competitors' signals. In other species, males synchronize their acoustic signals, potentially to avoid a degradation of the species-specific temporal pattern. Or, synchronization may occur because each male attempts to signal first. Such male behavior is likely to be advantageous, because in many species females prefer the leading signal when choosing between the synchronized signals of different males (Greenfield, 2002). Insect males that come into close contact often produce rivalry songs. These rivalry songs often have similarities to courtship signals but are usually easily distinguished from them. These similarities probably reflect the evolutionary origin of rivalry signals from courtship signals. The function of these rivalry songs might be to communicate the sender's sex to the competitor to avoid sexual harassment or they might function as an honest threat signal, analogous to roaring in red deer.

The third and most intensely studied aspect of acoustic communication in insects is communication with potential mates. Generally, males produce the majority of signals in all these communication systems. The underlying cause of this asymmetry between the sexes is the differential investment of males and females in their offspring. Female reproductive success is mainly limited by egg number and thus the amount of resources females can invest. Male reproductive success, in turn, is mainly limited by the number of mates a male can gain. Due to this difference between the sexes, selection on males to attain a larger number of matings is comparatively strong. For this reason, males signal to attract females, court them, and in some cases even consistently harass them. Due to sexually active males, females need not invest much in finding mates, and can optimize mate choice. In response to male acoustic signaling, responsive females of many species approach the males phonotactically. In several groups, females have evolved acoustic response signaling. This behavior probably has the advantage that in these cases the males have to accomplish the potentially dangerous phonotaxis.

Potential information contents of male acoustic signals include the male's position, his species identity, and his quality as a mate. For a male it is important to provide reliable information about his position, otherwise female phonotaxis might be impeded. However, predators or parasites might also cue in on acoustic signals, hence a compromise between those two pressures should be expected in nature. Since males cannot benefit from matings with heterospecific

females, males should also be selected to produce species-specific songs. This selection pressure, together with female avoidance of hybridization, probably explains why acoustic courtship signals can often be used for species identification. As a result of female mate choice among conspecific males based on information on male quality contained in their acoustic signals, there is also selection on males to signal their quality honestly. Due to intense competition between males, sexual selection can be strong and lead to the comparatively fast evolution of elaborate acoustic ornaments equivalent to such complex visual ornaments as the peacock's tail.

The final question to be tackled in this article is why females can benefit from intraspecific mate choice based on the males' acoustic signals. As explained above, females usually cannot increase their reproductive success by mating with a larger number of males. However, they can potentially gain from mate selection if mates differ in their effects on female reproductive success. Such potential effects are generally classified into two categories, direct and indirect benefits. Direct benefits are those that allow the female to produce more or better-nourished offspring, and indirect benefits are ones that are due to differences in the genetic quality of the offspring. Theoretically, females can gain direct benefits, for example, if they prefer males that provide nutritious nuptial gifts, or males with a lower risk of transferring diseases during copulation, or males that enable females to minimize risk and energetic costs during phonotaxis by calling with signals that facilitate their location by the females. Indirect benefits can be due to heritable differences in male genetic quality, concerning either attractiveness or viability, or due to genetic compatibility with the female. However, there is an alternative to these explanations, which assume that the benefit of sexual selection accrues as an effect of female choice. Female preferences could in principle be due to pleiotropic effects (not selected side effects) that reflect the effects of other selection pressures that have shaped the nervous and sensory system.

In conclusion, signals in acoustic communication can serve various tasks. Often single types of signal or individual traits of signals are likely to be influenced by antagonistic selection pressures. Signals should for example be easy to locate for females but as difficult as possible to locate for predators and parasites. Likewise, signals should easily be recognized as species specific, and thus close to the species-average signal, but should be outstanding when intraspecific female choice is considered. Probably due in part to these antagonistic selection pressures and the strong sexual selection that acts on the males' acoustic courtship signals, variation in acoustic signals between species is enormous. Like the similarly variable morphological structures used in courtship and copulation, the acoustic signals are assumed to have evolved comparatively rapidly and can often be used as traits to distinguish closely related species.

Inspiration and Revelation

J Vickers, Hood Theological Seminary, Salisbury, NC, USA

Recently, there has been widespread disagreement among Christian theologians about where revelation is to be found; this variance has led to further disagreement about the nature of revelation. Thus theologians who believe that revelation is located primarily, if not exclusively, in scripture tend to have a propositional view of the nature of revelation, whereas theologians who believe that revelation is located primarily in divine activity in the world tend to have an event-oriented view of revelation. These disagreements have led many theologians to question the usefulness of the concepts of revelation and inspiration. Any useful account must therefore acknowledge the difficulties, and, if possible, provide a way to overcome at least some of them.

The Concept of Revelation in Everyday Discourse

Given that revelation and inspiration are heavily contested concepts in theology, it will be helpful to consider how the concept of revelation is used in everyday or ordinary discourse. A consideration of how revelation is used in everyday or ordinary discourse is important for two reasons. First and foremost, the ability to locate divine revelation depends on a prior understanding of what it is that constitutes revelation. This prior understanding derives directly from the usage of the term in everyday discourse. Thus a consideration of how the term is used in everyday discourse will shed light on how it can and should function in theological discourse. Second, a consideration of how revelation functions in everyday discourse will provide rich suggestions for resolving the disagreements that plague appeals to revelation and inspiration in theology.

In everyday discourse, the concept of revelation is closely tied to the activity of revealing. By definition, the content of a revelation is something that is disclosed by one person to another. Thus, a revelation is not like a rock or tree or some other aspect of the world that persons normally encounter without the help of others. Rather, as one scholar puts it, "In everyday language the main location of discourse about revelation is in the arena of interpersonal relations" (Abraham, 1982: 10). Otherwise put, the content of a revelation is primarily, though not exclusively, given by persons to other persons. It follows the schema, *m* reveals *a* to *n*. It will help, then, to pay attention to three aspects of the verbal form of the concept, i.e., *to reveal*.

The first thing to notice about the verb *to reveal* is that it is grammatically different from other verbs such as *to eat* and *to sleep*. Whereas *to eat* and *to sleep* are task verbs, *to reveal* is an achievement verb. Achievement verbs designate activities whose success depends entirely upon achieving certain goals. Task verbs designate activities often undertaken in an effort to bring about the goals designated by achievement verbs. In this respect, *to reveal* is more like *to educate* and *to heal* than it is *to lecture* and *to prescribe medication*. Consider the activities of educating and healing. Educators and physicians perform a variety of tasks in an effort to educate or to heal. However, educating and healing are achievements that are logically distinguishable from the many tasks that might be undertaken in an effort to achieve the desired goals in each case. Thus, an educator might give lectures, make assignments, grade and return papers and examinations, and so on, without achieving what she takes to be the goal of educating. Similarly, a doctor might prescribe medicine or exercise and not obtain the goal of healing. Educating and healing require the realization of goals in, through, and sometimes in spite of the tasks undertaken along the way. The same is true for revealing.

If revealing is an achievement verb, then it is safe to surmise that a variety of tasks might be undertaken in pursuit of the goals associated with revealing. Thus, George Mavrodes rightly revises the schema given above as follows: *m* reveals *a* to *n* by means of (through, etc.) *k*. In this schema, *k* signifies the tasks or activities by means of which or through which persons seek to reveal. Putting the matter this way shows up another grammatical difference between revealing and other activities such as sleeping or eating. Sleeping and eating, like whistling or singing,

Recently, there has been widespread disagreement among Christian theologians about where revelation is to be found; this variance has led to further disagreement about the nature of revelation. Thus theologians who believe that revelation is located primarily, if not exclusively, in scripture tend to have a propositional view of the nature of revelation, whereas theologians who believe that revelation is located primarily in divine activity in the world tend to have an event-oriented view of revelation. These disagreements have led many theologians to question the usefulness of the concepts of revelation and inspiration. Any useful account must therefore acknowledge the difficulties, and, if possible, provide a way to overcome at least some of them.

The Concept of Revelation in Everyday Discourse

Given that revelation and inspiration are heavily contested concepts in theology, it will be helpful to consider how the concept of revelation is used in everyday or ordinary discourse. A consideration of how revelation is used in everyday or ordinary discourse is important for two reasons. First and foremost, the ability to locate divine revelation depends on a prior understanding of what it is that constitutes revelation. This prior understanding derives directly from the usage of the term in everyday discourse. Thus a consideration of how the term is used in everyday discourse will shed light on how it can and should function in theological discourse. Second, a consideration of how revelation functions in everyday discourse will provide rich suggestions for resolving the disagreements that plague appeals to revelation and inspiration in theology.

In everyday discourse, the concept of revelation is closely tied to the activity of revealing. By definition, the content of a revelation is something that is disclosed by one person to another. Thus, a revelation is not like a rock or tree or some other aspect of the world that persons normally encounter without the help of others. Rather, as one scholar puts it, "In everyday language the main location of discourse about revelation is in the arena of interpersonal relations" (Abraham, 1982: 10). Otherwise put, the content of a revelation is primarily, though not exclusively, given by persons to other persons. It follows the schema, *m* reveals *a* to *n*. It will help, then, to pay attention to three aspects of the verbal form of the concept, i.e., *to reveal*.

The first thing to notice about the verb *to reveal* is that it is grammatically different from other verbs such as *to eat* and *to sleep*. Whereas *to eat* and *to sleep* are task verbs, *to reveal* is an achievement verb. Achievement verbs designate activities whose success depends entirely upon achieving certain goals. Task verbs designate activities often undertaken in an effort to bring about the goals designated by achievement verbs. In this respect, *to reveal* is more like *to educate* and *to heal* than it is *to lecture* and *to prescribe medication*. Consider the activities of educating and healing. Educators and physicians perform a variety of tasks in an effort to educate or to heal. However, educating and healing are achievements that are logically distinguishable from the many tasks that might be undertaken in an effort to achieve the desired goals in each case. Thus, an educator might give lectures, make assignments, grade and return papers and examinations, and so on, without achieving what she takes to be the goal of educating. Similarly, a doctor might prescribe medicine or exercise and not obtain the goal of healing. Educating and healing require the realization of goals in, through, and sometimes in spite of the tasks undertaken along the way. The same is true for revealing.

If revealing is an achievement verb, then it is safe to surmise that a variety of tasks might be undertaken in pursuit of the goals associated with revealing. Thus, George Mavrodes rightly revises the schema given above as follows: *m* reveals *a* to *n* by means of (through, etc.) *k*. In this schema, *k* signifies the tasks or activities by means of which or through which persons seek to reveal. Putting the matter this way shows up another grammatical difference between revealing and other activities such as sleeping or eating. Sleeping and eating, like whistling or singing,

are activities that are often, in a manner of speaking, complete in themselves. It is entirely acceptable simply to speak of persons sleeping and eating. It is not necessary to say anything else in order to have a sense of completeness about such activities. Persons eat and sleep, whistle and sing. They do not simply reveal. It makes perfect sense to say, *Sarah sleeps* or *Sarah eats*. On the contrary, *Sarah reveals* is a grammatically incomplete proposition. Grammatically speaking, *Sarah reveals* requires an object if it is to be coherent.

When undertaken in the context of interpersonal relations, revealing is generally, but not always, a reflexive activity. Otherwise put, in the context of interpersonal relations, persons generally reveal themselves to others. To be sure, persons might reveal the location, say, of a secret treasure, but more often than not, persons reveal things about themselves. Thus *Sarah reveals* ***herself*** is a perfectly intelligible proposition. It is quite normal for persons to reveal to one another their desires, wishes, ambitions, thoughts, fears, pasts, and so on. Moreover, persons reveal such things about themselves through a variety of tasks, including speaking, writing letters, as well as nonlinguistic actions. Indeed, the common expression, 'actions speak louder than words,' points to the revelatory nature of nonlinguistic actions. In each case, however, the tasks of writing letters or speaking are distinguishable from the activity of revealing. As a reflexive activity, revealing takes place in and through writing, speaking, or nonlinguistic activities only if persons succeed in making something known about themselves through these activities. The crucial thing to see, however, is that revealing as a reflexive activity is not tied to any one task that persons might undertake in an effort to reveal themselves. On the contrary, persons reveal themselves through a variety of tasks. Indeed, the achievement of revelation, like the achievement of education or of healing, will often depend on the performing of a whole range of tasks.

At this stage, it is possible to give a descriptive account of Mavrodes' schema as follows. Revealing as a reflexive activity is achieved when, through the performing of an entire range of tasks, persons succeed in making themselves known to others. However, one final similarity between revealing and other achievement verbs needs to be noted. Like educating or healing, revealing as a reflexive activity is constituted by varying degrees of success. Thus, persons rarely, if ever, succeed in revealing everything there is to know about their selves. For that matter, even when the goal is to reveal only one aspect about a person's self, say, an ambition or a desire, persons often find it difficult to do so successfully. Even when they are exceedingly careful in their choice of words or in their nonlinguistic activities, persons are often surprised to learn that others understood them in a markedly different way than they intended themselves to be understood. To correct such misunderstandings, persons often find that it is necessary to reveal more about themselves. Success in revelation often depends on how much else is known about the person attempting to reveal her (or his) self.

Revelation and Inspiration in Theological Discourse

The history of the concepts of revelation and inspiration in theological discourse are closely intertwined. Three major developments in this history are especially important. The first development concerns the distinction between what is sometimes referred to as general revelation on the one hand, and special revelation on the other. It is common to associate the emergence of this distinction with the late medieval Catholic theologian Thomas Aquinas, although the distinction certainly shows up in the works of theologians who pre-date Aquinas. On this distinction, human persons can purportedly know some things about God, e.g., that God exists, that God is eternal and the like, simply by observing the creation or by attending to moral conscience. However, because there are many things concerning God that human persons cannot know by observation of the natural order, e.g., what God's intentions are towards human persons, there is also need for special revelation. For Aquinas, as for most Catholic theologians after him, special revelation takes place in the Incarnation, crucifixion and resurrection of Jesus Christ as disclosed in the scriptures and in church tradition.

The second major development worth noting takes place as a result of the Protestant Reformation. Unlike Aquinas and other Catholic theologians, Protestant theologians, following Martin Luther and John Calvin, have often restricted special revelation to scripture, eliminating as viable sources of divine revelation general revelation through creation or through moral conscience on the one hand, and special revelation in church tradition on the other. In an effort to secure scripture as the one reliable locus of divine revelation, many Protestant theologians developed and deployed theories of divine inspiration. On these theories, the scriptures could be relied upon as disclosing knowledge of God because God had inspired the authors of scripture. Consequently, theologians came to associate divine revelation almost exclusively with the inspired propositions set down in scripture.

The third major development in the history of the concepts of revelation and inspiration in Christian theology occurs in the mid-20th century. Beginning

as far back as the 17th century, the rise of modern biblical criticism caused many to call into question prevailing theories of divine revelation and inspiration. By the 20th century, the notion that divine revelation was located primarily, if not exclusively in scripture, was largely discredited. To be sure, some theologians defended the notion of propositional revelation vociferously, but the vast majority of theologians either gave up on divine revelation and inspiration altogether, or they began to theorize about other, nonpropositional forms of revelation. Two leading nonpropositional theories about the loci of divine revelation quickly emerged. One group of theologians, following the 19th century German theologian Friedrich Schleiermacher, sought to relocate divine revelation in experience. Another group of theologians emphasized what came to be known as 'the mighty acts of God in history' as the primary, if not exclusive, locus of divine revelation. Thus, by the mid-20th century, divine revelation was said to occur either in and through experience or in and through historical events, but not in and through the propositions given in scripture.

Revelation and the Word of God: A Way Forward

As an achievement verb, revelation cannot be strictly identified with any one task by means of which persons strive to reveal themselves. Indeed, like educating and healing, revealing is an activity accomplished through an entire range of tasks, including both verbal and nonverbal activities. Persons reveal themselves through their words *and* their actions. Consequently, it is difficult to see why accounts of divine revelation should limit themselves to one divine activity designed to achieve revelation. Put simply, it is conceptually odd to think that God only reveals God's self by inspiring prophets to set down propositions about God in scripture, or that God only reveals God's self through experience or through mighty acts performed in human history. It is theologically more productive, not to mention more conceptually compelling, to allow to God the same range of tasks or activities for revealing God's self that we normally allow to human persons. Otherwise put, useful accounts of divine revelation cannot exclude the tasks undertaken by God to reveal God's self in and through creation and the moral law within, in and through the inspiring of prophets and apostles, in and through the activities of God in human history and in human experience, and ultimately in and through the Incarnation of the Word of God. Going forward, what is needed is an account of divine revelation that refuses to limit divine revelatory activity to any one locus, taking seriously the manifold ways that God has sought to make God's self known to human persons.

Institutional Talk

I Magalhães, Universidade de Brasilia, Brasilia, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Institutional talk has been analyzed extensively by conversational analysts. Drew and Heritage (1992: 3–4) define it in the following way: "the institutionality of an interaction is not determined by its setting. Rather, interaction is institutional insofar as participants' institutional or professional identities are somehow made relevant to the work activities in which they are engaged." By disembedding talk from its institutional setting, this view misses the real point about institutional language: the fact that it is situated (Gumperz, 1982) (*see* **Context Principle; Context, Communicative**).

Institutional talk is embedded in power relations, and in order to understand what is really at stake, these relations have to be made explicit. Fairclough (1989) draws attention to the different meanings of the term 'power.' We can think of physical power, as

as far back as the 17th century, the rise of modern biblical criticism caused many to call into question prevailing theories of divine revelation and inspiration. By the 20th century, the notion that divine revelation was located primarily, if not exclusively in scripture, was largely discredited. To be sure, some theologians defended the notion of propositional revelation vociferously, but the vast majority of theologians either gave up on divine revelation and inspiration altogether, or they began to theorize about other, nonpropositional forms of revelation. Two leading nonpropositional theories about the loci of divine revelation quickly emerged. One group of theologians, following the 19th century German theologian Friedrich Schleiermacher, sought to relocate divine revelation in experience. Another group of theologians emphasized what came to be known as 'the mighty acts of God in history' as the primary, if not exclusive, locus of divine revelation. Thus, by the mid-20th century, divine revelation was said to occur either in and through experience or in and through historical events, but not in and through the propositions given in scripture.

Revelation and the Word of God: A Way Forward

As an achievement verb, revelation cannot be strictly identified with any one task by means of which persons strive to reveal themselves. Indeed, like educating and healing, revealing is an activity accomplished through an entire range of tasks, including both verbal and nonverbal activities. Persons reveal themselves through their words *and* their actions. Consequently, it is difficult to see why accounts of divine revelation should limit themselves to one divine activity designed to achieve revelation. Put simply, it is conceptually odd to think that God only reveals God's self by inspiring prophets to set down propositions about God in scripture, or that God only reveals God's self through experience or through mighty acts performed in human history. It is theologically more productive, not to mention more conceptually compelling, to allow to God the same range of tasks or activities for revealing God's self that we normally allow to human persons. Otherwise put, useful accounts of divine revelation cannot exclude the tasks undertaken by God to reveal God's self in and through creation and the moral law within, in and through the inspiring of prophets and apostles, in and through the activities of God in human history and in human experience, and ultimately in and through the Incarnation of the Word of God. Going forward, what is needed is an account of divine revelation that refuses to limit divine revelatory activity to any one locus, taking seriously the manifold ways that God has sought to make God's self known to human persons.

Institutional Talk

I Magalhães, Universidade de Brasilia, Brasilia, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Institutional talk has been analyzed extensively by conversational analysts. Drew and Heritage (1992: 3–4) define it in the following way: "the institutionality of an interaction is not determined by its setting. Rather, interaction is institutional insofar as participants' institutional or professional identities are somehow made relevant to the work activities in which they are engaged." By disembedding talk from its institutional setting, this view misses the real point about institutional language: the fact that it is situated (Gumperz, 1982) (*see* **Context Principle; Context, Communicative**).

Institutional talk is embedded in power relations, and in order to understand what is really at stake, these relations have to be made explicit. Fairclough (1989) draws attention to the different meanings of the term 'power.' We can think of physical power, as

of one person over another. However, institutional power is usually enacted by consent. Power can be seen as both a product and a process by which the members of an institution organize their activities. For Foucault (1980: 98), power is exercised through a "net-like organisation," in which individuals are participants both as its "consenting target" and as the "elements of its articulation." This means that the subaltern positions in an institution (for example, patients in hospitals) contribute in certain ways to unequal power relations, by accepting as the natural order of things that doctors in "standard medical interviews" should have interactional control over the distribution of turns at talking, the selection and change of topics, and what kind of questions are answered (Fairclough, 1992: 138–139) (*see* **Power and Pragmatics; Discourse, Foucauldian Approach**).

As Mey notes, "the case of the medical interview is an outstanding instance of the institutionalized discourses in which the value of the individual's linguistic expression is measured strictly by the place he or she has in the institution. Only utterances which meet the criteria of the official discourse are allowed . . ." (Mey, 2001: 301).

Institutional talk is often gendered (Graddol and Swann, 1989). In the following example in my study of doctor–patient communication in Brazil, a doctor manipulates a woman into breastfeeding her baby, against her argument that she has to go to work (Table 1) (Magalhães, 2000: 159–163).

The doctor's male authority is manifested in an absolute interactional control, in terms of the topic and the turns at talking. In terms of the topic, he controls entirely what is talked about, commanding the mother, with verbal and nonverbal arguments (for example, by hitting his desk), to go back to breastfeeding.

The doctor furthermore controls turn-taking by overlapping speech, as when the woman notes that when she breastfeeds, the baby is still hungry. Overall in this example, we see how institutional talk is embedded in power relations by means of the interactional control exercised by those in power (*see also* **Gender and Language**).

Table 1 Example of institutional talk in doctor–communication

Summary of the woman's arguments	*Summary of the doctor's arguments*
She has to go to work. Work demands involvement, making it difficult to go on breastfeeding. She is weak, and her milk does not feed the baby properly. So the baby is hungry	Breastfeeding must be applied in all cases. The doctor does not discuss the woman's particular case. In fact, he does not even explain why the baby has to be breastfed. He counters her argument that her milk does not feed the baby properly by saying that it does

Integrational Linguistics (IL)

R Sackmann, Freie Universität Berlin, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Integrational Linguistics (IL), developed by the German linguist Hans-Heinrich Lieb and others since the late 1960s, is a general, non-generative approach to linguistics that aims at providing a comprehensive theoretical framework for the description of arbitrary languages. The name 'Integrational Linguistics' has been used in publications since 1977, antedating the use of the same name for an entirely unrelated approach originating from the work of Roy Harris.

Over the past three decades, IL has developed (i) a general theory of language (Integrational Theory of Language) that covers both the systematic features of language systems and the phenomenon of language

variability in a unified way, and (ii) a theory of grammars (Integrational Theory of Grammars), understood as part of a theory of linguistic descriptions. The separation of a theory of language from a theory of grammars is a major feature of IL by which it differs from approaches with a generative orientation.

After an initial emphasis on the Integrational Theory of Grammars, work in IL has been characterized by a steady and continuous refinement of the Integrational Theory of Language based on empirical data from typologically diverse languages, avoiding basic revisions as they occurred in Chomskyan Generative Grammar.

General Features

The term 'integrational' is motivated by the following 'integrative' features of the approach as a whole:

1. Linguistics is construed as a well-defined discipline in its own right but is also placed within a wider system of interrelated disciplines. Contrary to the conceptions proposed by Noam Chomsky, which reduced linguistics first to psychology and later to biology, IL adopts a non-reductionist stance: such disciplines as biology, psychology, sociology, and anthropology are conceived as neighboring disciplines of linguistics, disciplines that each share a branch with linguistics (biolinguistics, psycholinguistics, sociolinguistics, etc.); and linguistics itself is construed as a branch of (human) semiotics.
2. A broad view of linguistic subject matter is taken: linguistics deals with all aspects of natural languages that are directly or indirectly relevant to their use. This includes not only systematic aspects of languages, i.e., aspects related to structural properties of 'linguistic systems' in a traditional sense, but also the internal variability of languages; the relationship between languages and the structure of the societies in which they are used; the relationship between communication in a language and actions by, or psychological processes in, a speaker; the neurophysiological and psychological foundations for learning and mastering a language; and aspects of the development and decline of languages.
3. It is assumed that each major aspect of natural languages (the morphological, the syntactic, the semantic, etc.) must be characterized in its own right, which includes showing its interrelations with other aspects. This is achieved in IL by developing separate but interrelated theories for each major aspect (Integrational Morphology, Integrational Syntax, etc.) that form coherent parts of a larger 'Integrational Theory of Language Systems' (see below).
4. A nonlinguistic theory (e.g., a psychological or sociological theory) may be integrated with a theory of language, and relevant parts of a general theory of language are, as a rule, integrated with each language description (itself a theory of one or more individual languages or language varieties): the language description is formulated 'in terms of' a theory of language, that is, it incorporates and employs terms, definitions, assumptions, and theorems from the underlying general theory. This idea of 'theory integration' is made precise in the Integrational Theory of Grammars.

IL is opposed to basic assumptions that characterize linguistic cognitivism in its 'non-intentionalist varieties:' the objects of linguistics are construed not as mental or neurophysiological mechanisms or corresponding 'representations,' but as natural languages conceived as abstract, extramental entities; a grammar of a language is an empirical theory (ideally, an empirical axiomatic theory) of that language, in a sense of 'theory' that requires sets of statements among the theory's components (see Lieb, 1974/1976). Hence, the traditional generative as well as the more recent cognitive conceptions of grammars as algorithms are rejected: from the very beginning, grammars were construed in IL not as algorithms but as 'declarative' theories (theories that make claims formulated as statements, and carefully keep apart a description from the entities described), a position that is currently being seriously considered also in other approaches. Natural languages are seen to arise from abstract, extramental objects (such as phonetic sounds). However, these objects are associated with concrete physical events (such as utterances of phonetic sound sequences) and are involved in the content of mental states or events that are connected with language use and knowledge. IL is thus compatible with a non-cognitivist, 'intentionalist' mentalism that may be proposed as typical of a 'New Structuralism.' (See Lieb, 1992a, 1992b for a more detailed discussion.)

Given these characteristics, the common but rather constrained distinction between 'formalist,' 'functionalist,' and 'cognitivist' schools of linguistics does not apply to IL, which exhibits features of all three kinds of approaches. Major advantages of IL may be seen in (i) the fact that it was developed in view of the full spectrum of linguistic diversity from the outset, (ii) its integration of all levels of linguistic description (from phonetics to sentence semantics) within a unified theoretical framework, (iii) its inclusion of both system-based and non-system-based properties of

languages, (iv) its development both of a theory of language and a theory of linguistic descriptions, and (v) the ontological explicitness and consistency of all its theories, making it a framework suitable for the description of individual languages as well as for contrastive linguistics, linguistic typology and universals research.

IL adopts a positive and constructive attitude toward Western linguistic tradition and regards itself as a part of this tradition. In syntax and morphology, the Integrational Theory of Language centers around a formally explicit, consistent, and vastly enriched version of theoretical conceptions underlying actual grammar writing since antiquity, embedding them in a broader scientific context that comprises linguistics and its neighboring disciplines; and the Integrational Theory of Grammars applies modern means to account for the intricacies of actual descriptive work.

Integrational Linguistics strives for logical soundness even in informal descriptions and makes extensive use of naive set theory in formulating its theories in order to achieve explicitness and clarity.

The Integrational Theory of Language

The Integrational Theory of Language contains two major subtheories: (i) the Integrational Theory of Linguistic Variability, which is 'conflated' with (ii) the Integrational Theory of Language Systems. One of the most distinctive features of the Integrational Theory of Language is its adherence to ontological explicitness and constructiveness: the ontological status of every linguistic entity postulated by the theory is clearly determined (explicitness), and every entity is a logical or set-theoretical construct ultimately related to a small number of sets of basic entities that include, in particular, objects and events in space-time (constructiveness).

The Integrational Theory of Linguistic Variability

From its inception, IL has regarded linguistic variability, i.e. the changeability of languages along dimensions such as time, geographical space, social stratification etc., as an essential property of natural languages that has to be treated in any realistic theory of language; certain idealizations, such as Chomsky's 'completely homogeneous speech-community,' are rejected.

The Integrational Theory of Linguistic Variability thus aims at providing a theoretical framework for variation research (including studies in sociolinguistics, dialectology, and historical linguistics) and a basis for a realistic theory of language systems. The theory centers around the notion of 'idiolect,' in a specific sense of the term that avoids traditional problems: an idiolect is a homogeneous part of an individual speaker's share of a language (a speaker's total share of a language, called a 'personal variety,' is not an idiolect in this sense but is a set of idiolects). Such an idiolect, understood as an individual (linguistic) means of communication of a person during a certain period of time, simultaneously belongs to a certain period of the language, to a certain dialect, sociolect, register, medial variety, etc. A natural language (understood as a historical language during the entire span of its existence, or a period – a major temporal part – of a historical language) is construed as a set of idiolects, and each variety of the language is a subset of the language. Sets of idiolects (such as languages and their varieties) are called 'communication complexes.' The varieties of a language are given through its 'variety structure': a classification system whose source is the language itself.

Ontologically, an idiolect is construed as a (possibly infinite) set of abstract sentences: form-meaning pairs consisting, in the case of a spoken rather than a written or signed idiolect, of a structured phonetic sound sequence and a meaning of this sequence. For each idiolect in a language, there is a system (idiolect system) that specifies which form-meaning pairs are elements of the idiolect. Every idiolect system consists of (technically: is an *n*-tuple whose components are) a phonetic, phonological, morphological, syntactic, lexico-semantic, and sentence-semantic part; and each part determines a different type of properties that the form-meaning pairs must have in order to belong to the idiolect. In written idiolect systems, the phonetic and phonological parts are replaced by a graphetic and a graphematic part, in signed idiolect systems by a cheremic and a cherematic part. (There may be other components in addition to the ones listed above; the precise structure of idiolect systems is a matter of ongoing research.) The parts of an idiolect system are grouped into the sound system (script system, chereme system), the morphosyntactic (or grammatical) subsystem, and the semantic subsystem of the idiolect system. (There is no pragmatic part or subsystem – 'pragmatic' properties of form-meaning pairs, as far as they are determined by the idiolect system itself, are covered by the semantic subsystem, or else indirectly by the idiolect's place in the variety structure.) Finally, a *system for* a language (or language variety) is a construct of properties shared by every *system of* every idiolect in the language (or language variety). Idiolects, varieties, languages, and their systems are all construed as extramental and abstract.

Systems of idiolects (idiolect systems) and systems for languages differ from each other both ontologically and in their relation to speakers' minds. Idiolect

systems are *n*-tuples (as specified above) whereas language systems are sets of properties of such *n*-tuples. Moreover, for every idiolect that is a means of communication for a given speaker, there must be a (psychological and physiological) internal basis in the speaker that corresponds to a system of this idiolect, but there is no such internal basis for entire language systems. From an IL point of view, distinguishing between language systems, idiolect systems, idiolects (themselves no systems), and speaker-internal bases for idiolects is a cornerstone for a realistic theory of natural languages and language use. (For a full representation of the Integrational Theory of Linguistic Variability and discussion of rival theories, see Lieb, 1993a; for the conceptions of languages and idiolects, see also Lieb, 1983a: part A.)

The Integrational Theory of Language Systems

The Integrational Theory of Linguistic Variability is conflated with the Integrational Theory of Language Systems. The latter is concerned mainly with (i) making general assumptions on the properties of idiolect systems in arbitrary languages and (ii) developing a conceptual framework, and corresponding terminology, for their description.

The well-known problems in defining a truly universal terminology (applicable in the description of arbitrary languages) in the face of linguistic diversity are tackled in IL by making a number of essential metatheoretic distinctions, implicit in linguistic tradition but typically blurred in modern approaches. Most importantly, a distinction is made between the *definition* of a term and the *identification* of corresponding linguistic entities in given idiolect systems. For example, terms such as 'phoneme,' 'suffix,' 'verb,' 'singular,' 'accusative,' etc. are construed not as categorial terms (denoting sets of linguistic entities) but as names of two-place relations ('is-a-phoneme-of,' 'is-a-suffix-of,' etc.) between linguistic entities and idiolect systems *S* (e.g., SLEEP is-a-verb-of S_E, SCHLAFEN is-a-verb-of S_G, where S_E and S_G are, respectively, an English and a German idiolect system: one and the same relation [is-a-]verb[-of] holds between SLEEP and S_E, SCHLAFEN and S_G, etc.). Names for categories of a given idiolect system are then derived from such relational terms: the expression 'verb-of-S_E' denotes the set of all verbs of S_E (a category), i.e., denotes the set of all linguistic entities that are related to idiolect system S_E by the relation [is-a-] verb[-of]. While the relational term 'verb' is defined in the Integrational Theory of Language Systems so as to allow for *arbitrary* idiolect systems, the corresponding categories (verb-in-S_E, verb-in-S_G, etc.) must be *identified* in a grammar for individual idiolect systems, and the identifying properties may vary greatly among the systems of idiolects in different languages or even within a single language. It is a task not of a general theory of language but of theories of individual languages or language varieties – e.g., of individual grammars – to formulate identifying properties for the entities (categories, etc.) postulated for the idiolect systems of a given language (or variety). (Consider, for instance, a language in whose idiolect systems *S* all infinitive forms of verbs – and only such forms – have a certain prefix, giving rise to an identifying property for the category infinitive-in-*S* in the idiolect systems of this language. Clearly, this criterion should not be used to define the term 'infinitive' in a general theory of language.) Given this distinction, a term like 'verb' may be *defined* by means of word- or sentence-semantic criteria; the syntactic nature of the corresponding categories in individual idiolect systems is still guaranteed by the fact that the categories can be *identified* by resort to the syntactic means of the idiolect systems (morphological marking, word order, intonation) and, possibly, properties of lexical meanings. Defining a term in a general theory of language does not, however, imply that there are corresponding entities in all idiolect systems (for instance, we can formulate a general definition of 'adjective' although there may be languages without adjectives).

The elements of a category in a given idiolect system may, and usually will, have additional relevant properties not needed for identifying the category. (In the above example, the infinitive forms may show certain tense distinctions.) Such properties must still be included in a *complete characterization* of the category. Finally, each entity proposed by a general theory of language or by a theory of an individual language, variety, or idiolect should also be *justified* by metatheoretic considerations. Consider, for example, the set of all adjective forms of a given English idiolect system whose sound sequences start with /bl/. Such a set should hardly be postulated as a syntactic category of this idiolect system, even though the set would easily be identified, and a corresponding term would easily be defined.

From an IL point of view, distinguishing between the definition of a term, the identification and characterization of a corresponding entity in an individual idiolect system, and the justification for postulating such an entity in a theory of a specific language, is a prerequisite both for formulating a general theory of language (one of the main goals of linguistics) and for successfully integrating theories of individual languages or language varieties with such a theory. Integrational Linguistics appears to be the only modern approach to explicitly adopt the fourfold distinction between definition, identification, characterization

and justification, implicit in Western linguistic tradition with its insistence on the *semantic* definition of many general terms used in identifying *syntactic* entities as described in individual grammars. (For a detailed discussion of the underlying metatheoretic principles, see, in particular, Budde, 2000: chapter 1; for an application in a general theory of parts of speech, using German for orientation, see Budde, 2000: chapters 2–10.)

Reflecting the basic structure of spoken idiolect systems (see above), the Integrational Theory of Language Systems comprises Integrational Phonology, Integrational Morpho-Syntax (with Integrational Morphology and Integrational Syntax), and Integrational Semantics (Integrational Lexical Semantics, including morpho-semantics and word semantics, and Integrational Sentence Semantics). For medial types of idiolect systems other than the spoken one, suitable subtheories – corresponding to Integrational Phonology – are provided for but have not yet been worked out in detail (Integrational Graphematics for written, Integrational Cherematics for signed idiolect systems).

The most detailed representation to date of the Integrational Theory of Language Systems as a whole (excluding Integrational Phonology) is found in Lieb (1983: parts B to F); for Integrational Syntax see also Lieb (1993b), for Integrational Semantics Lieb (1979; 1980; 1992c). Integrational Phonology (the last component of the theory to be developed) is presented in Lieb (1999; 2005a). Sackmann (2005b) is an introduction to Integrational Syntax and Morphology, including more recent developments, that contains numerous examples of analyses. For major applications of IL in linguistic description, see, for example, Richter (1988), Moltmann (1992), and Eisenberg (1998/1999), concentrating on German; Sackmann (2005a) for Mandarin Chinese; see also the contributions in Sackmann (ed.) (2005) and the book series *Studies in Integrational Linguistics* in general. The conception of (morphological and syntactic) paradigms, fundamental in IL, has recently been further elaborated in Lieb (2005b).

Integrational Phonology Integrational Phonology is a 'declarative' two-level phonology that postulates two distinct levels (or 'parts') in the sound system of any idiolect system, a less abstract phonetic and a more abstract phonological one. Phonetic and phonological sounds are both conceived as sets of auditory properties of speech-sound events, hence, as abstract real-world entities. (Speech-sound events are concrete entities, located in space-time.) Phonological sounds differ from phonetic ones by a higher degree of abstraction: While sounds on the phonetic level (i.e., part) of an idiolect system contain all properties that characterize normal utterances of entities of the idiolect system, phonological sounds contain only those properties that are functional in the idiolect system, that is, are relevant with respect to distinctions in the morphological, syntactic, or semantic parts of the system.

Phonological words and morphs (on the phonological level) as well as phonetic words (on the phonetic level) are construed as 'structured sound sequences,' that is, ordered pairs consisting of (1) a phonetic or phonological sound sequence (called the 'basis' of the morph or word) and (2) a phonetic or phonological structure of the sound sequence – itself a pair of (2a) a constituent structure and (2b) an intonation structure of the sound sequence. ('Sequence' is understood in the Integrational Theory of Language in a specific, set-theoretical sense that allows for the limiting cases of empty and one-member or 'unit sequences.') The constituent structure relates parts of the sound sequence to one of the sound categories Vocalic-in-*S*, Consonantal-in-*S*, and VocalicGroup-in-*S*, thereby determining a syllable sequence (possibly empty) for the sound sequence. The sound categories (simultaneously belonging to the phonetic and the phonological level) are uniformly construed as sets not of individual sounds but of sound *sequences* of the idiolect system, allowing a treatment of affricates and long consonants (elements of Consonantal-in-*S*), diphthongs and long vowels (elements of Vocalic-in-*S*) and the like alongside simple vowels and consonants. The intonation structure assigns sets of 'auditory values' (pitches, degrees of loudness, phonation modes etc.) to the syllables of a (syllabic) sound sequence identified by the constituent structure. Prosodic phenomena in both accent languages and tone languages are then treated in a unified way: differences of tone or stress are represented through sets of auditory values directly within a specific component of a phonological word, namely, the phonological intonation structure, which is properly linked to the (syntactic) intonation structures of syntactic units in which the phonological word occurs; and tone languages differ from accent languages mainly in the way phonological intonation structures are 'processed' in syntactic intonation structures. The constituents of a structured sound sequence are connected through phonological relations (p-nucleus, p-complement, p-modifier).

The phonetic-phonological properties of an idiolect system are to a large degree determined by the way sound sequences combine to form more complex ones, and the way phonetic sound sequences are related to phonological ones. There is a 'connection function' on the phonological level that takes pairs of

structured sound sequences and assigns to each pair another such sequence, and a 'connection function' on the phonetic level that takes such pairs and assigns to each pair a *set* of structured sound sequences. Both levels are connected through a 'variant relation' relating structured phonetic sound sequences to structured phonological sound sequences. While the two connection functions jointly represent the 'phonotactics' of the idiolect system, the variant relation is only partly analogous to the 'allophone' relation in structuralist phonology and avoids its problems (treatment of diphthongs, affricates etc.) by connecting structured phonetic with structured phonological sound *sequences* instead of connecting individual sounds. Phonetic variants of a complex structured phonological sound sequence may be determined not only phonetically but also phonologically, by underlying sequences on the phonological level. The variant relation is postulated as a third component of the sound system of an idiolect system, in addition to its phonetic and phonological parts.

Integrational Syntax and Morphology Integrational Syntax is akin in spirit to Lexical Functional Grammar, notwithstanding basic differences, and includes essential ideas of Valency Grammar. Among modern approaches to syntax, Integrational Syntax may well be closest to the grammatical tradition as it has developed in the West since antiquity. In particular, Integrational Syntax is Word-and-Paradigm, an orientation that has recently been gaining followers also elsewhere in linguistics. Integrational Syntax is a surface syntax: no 'deep structures' and no empty syntactic units or categories are allowed; true, an 'empty phonological word,' properly defined, is assumed for the treatment of phenomena such as ellipsis, and the empty sequence is used to deal with so-called optional complements. Integrational Syntax is also a 'syntax as a basis for semantics' in the sense that every meaning of a complex syntactic unit is obtained from the lexical meanings of its primitive meaningful parts on the basis of one of its structures. (The nature of lexical meanings is specified in Integrational Lexical Semantics, while ontological questions regarding syntactic meanings and the details of syntactic-semantic meaning composition are treated in Integrational Sentence Semantics.)

Among the syntactic entities postulated in Integrational Syntax for the syntactic part of arbitrary idiolect systems, there are: syntactic base forms, syntactic units, syntactic paradigms, lexical words, syntactic categories (either syntactic unit categories or word categories), syntactic structures, and syntactic functions.

A syntactic unit of an idiolect system is a sequence of syntactic base forms. (Again, unit sequences, but not the empty sequence, are allowed as a limiting case of syntactic units, that is, a syntactic unit may contain a single syntactic base form.) In a system of a spoken idiolect, the syntactic base forms are precisely the phonological words occurring in the phonological part of the system (analogously, for systems of written and signed idiolects).

It is an essential feature of Integrational Syntax that a clear distinction is made between lexical words and forms of lexical words (called 'syntactic word forms' or simply 'syntactic words'): every lexical word is an ordered pair consisting of a syntactic paradigm or 'word paradigm' (the form component of the word) and a concept that is a meaning of the paradigm (the meaning component of the word); a syntactic paradigm is a (non-empty) set of pairs, each consisting of a syntactic word form and a 'categorization' of the word form, that is, a set of syntactic categories such that the word form is an element of each category in the set; and any syntactic word form is also a syntactic unit, hence, a sequence (possibly, a unit sequence) of syntactic base forms (phonological words in the case of spoken idiolects). A given syntactic word form may combine with several categorizations within a single paradigm (syncretism); and a single paradigm may have a number of different meanings (polysemy), which leads to the same number of different lexical words (identical in their form components). Both the notion of paradigm and the notion of concept are generalized so as to allow for lexical words also where traditionally one would not speak either of a paradigm or of a lexical meaning.

Given the distinction between syntactic units (including syntactic word forms) and lexical words, two main types of syntactic categories are postulated for the syntactic part of any idiolect system. Type 1 syntactic categories (also called 'syntactic unit categories') are sets of syntactic units of the idiolect system, and include the syntactic constituent categories as well as word form categories like cases, numbers, tenses, and definiteness categories. The type 1 syntactic categories of an idiolect system are given through a classification system (a system of cross- and subclassifications) on the set of all syntactic units of the idiolect system, called the 'Syntactic Unit Ordering.' Type 2 syntactic categories (also called 'word categories') are sets of lexical words. They include the 'parts of speech' of the idiolect system and their subcategories. The type 2 categories are given by the 'Lexical Word Ordering,' a classification system on the set of all lexical words of the idiolect system. Both the Syntactic Unit Ordering and

the Lexical Word Ordering are components of the syntactic part of an idiolect system.

Any syntactic unit can be assigned at least one syntactic structure. The syntactic structures of a unit are to jointly represent all formal information (including intonation) that is relevant with respect to the syntactic meanings of the unit. This is achieved by construing the syntactic structures of a syntactic unit as triples consisting of (i) a constituent structure, (ii) a marking structure, and (iii) an intonation structure of the unit. The *constituent structure* identifies constituents of the unit by associating certain parts of the unit with syntactic constituent categories like Noun form, Verb form, Verb Group etc., and captures the positions of syntactic base forms within the unit. The formal conception of constituent structures developed in IL allows for easy surface treatment of discontinuous constituents (whose proper treatment was a key motivation, in early Generative Grammar, for deep structures) and avoids any restriction to binary branching with its well-known empirical problems. The *marking structure* contains additional categorial information beyond what is provided by the constituent structure. Each primitive constituent of the syntactic unit, that is, each occurrence of a form of a lexical word in the unit, is assigned a 'marking': a set of pairs each consisting of two sets of categories. The first set contains syntactic unit categories of which the word form itself is an element; more specifically, the set is identical with a categorization the word form has in the paradigm of a lexical word to which the word form belongs; if the word form has several categorizations in the paradigm, then all these categorizations appear as first components of pairs in the marking of the primitive constituent, thus, the marking has several elements. The second set contains word categories (in particular, government categories) characterizing the lexical word itself. Finally, the *intonation structure* is a sequence of modified intonation structures of the syntactic base forms occurring in the syntactic unit. The syntactic intonation structure is crucial for syntactic accents and for the distinction of sentence types (as far as this is based on intonation patterns).

Traditional grammatical relations such as subject, object, attribute, etc. are reconstructed in Integrational Syntax as functions ('grammatical functions') taking 'syntactic quadruples' as their arguments. Each quadruple consists of (i) a syntactic unit (or concatenation of units) of an idiolect system, (ii) a syntactic structure the unit or concatenation has in the system, (iii) an assignment of lexical meanings to the primitive constituents contained in the unit given the structure and the system (called a 'lexical interpretation'), and (iv) the system itself. The values of such grammatical functions are two-(or more)-place relations among constituents of the syntactic unit. (Grammatical functions are only one type of 'constituent functions,' which also include 'scope functions' like negation and qualification, and 'phoric functions' like antecedent; and there are other types of syntactic functions besides the constituent functions.) Syntactic functions play a central role, via their semantic content, in the composition process by which syntactic meanings of a syntactic unit are constructed from the lexical meanings of its primitive constituents. Incorporating features of Valency Grammar, Integrational Syntax construes subject and object functions as derived from more basic complement functions that simultaneously cover all complements of a single verbal nucleus; it generalizes the notion of valency to arbitrary lexical words, excluding purely auxiliary words.

This reconstruction of traditional conceptions, which distinguishes between (universal) syntactic functions on the one hand and their values for individual syntactic quadruples on the other, again allows to formulate general *definitions* for the names of syntactic functions in the Integrational Theory of Language, and to *identify* their occurrences in the syntactic units of specific idiolect systems by statements in a grammar. Such identification, relative to the syntactic structure and lexical interpretation contained in a given syntactic quadruple, typically depends on the marking structure more than on other components of the syntactic structure, or the lexical interpretation. In particular, government categories, given through classifications in the Lexical Word Ordering and contained in the marking structure, are crucial to identifying the values of the complement functions relative to the syntactic quadruple. Type 1 categories, contained in the marking structure, may also play a role in the identification of syntactic function values. For example, the identification of subject constituents as opposed to object constituents may depend on case categories (cf. German *Der Kellner* [NOM] *mochte sie.* 'The waiter liked her.' vs. *Den Kellner* [ACC] *mochte sie.* 'The waiter she liked.').

Integrational Morphology, concerned with the analysis of phonological words (and other medial types of syntactic base forms) into meaningful parts, is largely analogous to Integrational Syntax. The morphological entities postulated for any idiolect system are morphological base forms, units, paradigms, categories, structures, and functions as well as lexemes. Morphological base forms (morphs) are entities of the same ontological type as syntactic base forms, structured phonological sound sequences in the case of a spoken idiolect; morphological units are sequences of morphological base forms; and 'lexemes' are conceived as ordered pairs consisting of a

morphological paradigm and a concept that is a meaning of the paradigm, similarly to the lexical words in syntax. For any syntactic base form there is a 'morphological analysis': a pair consisting of a morphological unit and a morphological structure of the unit. A morphological unit that is the first component in an analysis of a syntactic base form is a 'morphological word.' A morphological structure of a morphological unit is a triple consisting of a morphological constituent structure, marking structure, and intonation structure. Two main types of morphological categories are assumed. Type 1 morphological categories (also called 'morphological unit categories'), given through the 'Morphological Unit Ordering' of an idiolect system, are sets of morphological units; they include morphological constituent categories, maximally, Stem form, Affix form, and Stem Group, as well as possible subcategories of Stem form and Affix form. Cross-linguistically, there must be stem forms in the idiolect systems of any language whereas the categories Affix form and Stem Group need not occur. Type 2 morphological categories ('lexeme categories') are sets of lexemes and are given through the 'Lexeme Ordering' of the idiolect system. They include the top-level lexeme categories Stem and Affix (comparable to the parts of speech in syntax) and their subcategories. Morphological functions (e.g., morphological complement, modifier, and nucleus) are comparable to grammatical functions in syntax in taking 'morphological quadruples' as their arguments and assigning relations among morphological constituents as values. They figure, via their semantic content, in morphosemantic meaning composition.

The *lexicon* of an idiolect system is construed as a pair consisting of the *lexeme lexicon* and the *word lexicon*. The former is the set of all lexemes (hence, the source of the Lexeme Ordering), and the latter is the set of all lexical words (hence, the source of the Lexical Word Ordering), of the idiolect system.

Integrational Semantics Integrational Semantics treats lexical meanings (i.e., meanings of morphological or syntactic paradigms and their forms) as entities entirely different from syntactic meanings (meanings of simple or complex syntactic constituents obtained through syntactic meaning composition). Consequently, meaning composition, too, is construed differently for lexical and for syntactic meanings. Integrational Lexical Semantics (with Integrational Morphosemantics and Integrational Word Semantics as its parts) combines the psychological and the realist traditions in semantics. Lexical meanings are construed as concepts in a psychological sense: an n-place concept (with $n > 0$) is the property of being a (human) perception or conception in whose content a certain non-empty set of n-place attributes of real-world entities occurs as a subset. The set of attributes is called the (n-place) intension of the concept, and the set of real-world entities that have all attributes is called its (n-place) extension. The extension but not the intension may be empty. In the case of a 1-place concept, the attributes in the intension are properties, and the extension is a set of individual real-world objects. If $n > 1$, the attributes are n-place intensional relations between real-world entities, and the extension is the set of n-tuples of real-world entities among which the n-place relations in the intension hold. Such 'relational concepts' typically occur as lexical meanings of verbs and adpositions (prepositions, etc.) but also of other kinds of relational words. The only concept for which the notions of intension and extension are not defined is the (0-place) 'empty concept,' occurring as the meaning component of lexical words such as auxiliaries and modal particles, and of all affixes, that is, of linguistic entities whose contribution to meaning composition is not based on lexical meanings. Given the notion of empty concept, the IL conception of concepts is both flexible and powerful enough to assign meanings to lexical words of any kind.

A conception is a mental state, and a perception a mental event, located in the brain of an individual. By identifying concepts not with such mental entities but with (extra-mental) properties of mental entities, Integrational Lexical Semantics can account for the potential intersubjectivity of concepts, a problem that any psychological meaning conception must face: while perceptions and conceptions are tied to an individual, a concept may well be a property shared by perceptions or conceptions located in different individuals.

Lexical meaning composition is based on morphosemantic composition functions whose arguments are (n-tuples of) concepts and whose values are again concepts. Such semantic functions occur in the semantic content of morphological functions such as morphological complement, modifier, and nucleus, and operate on the basis of (morphological or semantic) application conditions.

In Integrational Sentence Semantics, sentence meanings are construed as intensional relations between potential utterances and potential speakers. For any syntactic unit that has a sentence meaning, the meanings of the unit jointly represent a necessary condition for successful utterances of the unit. Each (simple) sentence meaning consists of at least (i) a referential part: a set containing exactly one 'referential meaning' for each referential expression of the syntactic unit; (ii) a propositional part: a pair consisting of a directive part (determining a speech act type)

and a proposition; and (iii) a propositional background, consisting of what the speaker co-expresses with the proposition. The referential part and the propositional background of a sentence meaning may be empty.

Syntactic meaning composition is based on semantic composition functions associated with (i) the syntactic functions in an idiolect system, by the 'syntactic function interpretation,' (ii) with syntactic categories like tense or definiteness categories, by the 'syntactic category interpretation' (both are components of the sentence-semantic part of the idiolect system). Syntactic meaning composition starts from the lexical meanings of the primitive constituents in a syntactic quadruple: 'basic syntactic meanings' are pairs of a concept, assigned to a primitive constituent by the lexical interpretation, and a 'contextual embedding' of the concept that involves potential speakers and utterances. Next, basic syntactic meanings are transformed into 'intermediate syntactic meanings' for non-primitive constituents by means of syntactic-semantic composition functions that are associated in the idiolect system with syntactic functions such as complement and modifier. Finally, the intermediate (and, possibly, basic) meanings are further processed by semantic functions that are associated with the syntactic nucleus function, so as to yield 'complete syntactic meanings,' which are either referential meanings or sentence meanings.

It appears that Integrational Sentence Semantics combines the meaning-as-use tradition in semantics (relating sentence meanings to speakers and utterances) with features of the psychological tradition (lexical meanings as concepts in a psychological sense, speaker attitudes as essential to sentence meanings) and with features of the realist tradition (e.g., extramental status of lexical and of syntactic meanings, the compositionality principle for complex meanings).

The Integrational Theory of Grammars

Integrational Linguistics emphasizes the distinction between theories of language and theories of language descriptions. A description of a language is understood as a theory (formulated by the linguist) of the language; similarly, for descriptions of varieties or individual idiolects. Traditionally, grammars are most important among such descriptions, which also include descriptions of (parts of) the variety structure of a language, such as a description of a language's development in time or distribution in geographical space. 'Grammar' is here used in a broad sense, covering not only morphological and syntactic but also phonological and semantic descriptions. A description of the lexicon, i.e. a dictionary, is again construed as a theory of its object (see Drude, 2004). Since the Integrational Theory of Grammars deals with the relation between language descriptions and their objects, it presupposes both the Integrational Theory of Linguistic Variability and the Integrational Theory of Language Systems.

On an IL view, grammars have three fundamental properties:

1. Ideally, they are empirical axiomatic theories. IL does not propose to replace traditional, non-axiomatic grammars by axiomatic theories. Rather, an axiomatic format for grammars is seen as an ideal reference point for non-axiomatic, declarative grammars that allows for a more stringent formulation of such grammars, a formulation that avoids inconsistencies and circularities without having explicit resort to axiomatization. The empirical basis of grammars is ultimately seen in acts of communication on the one hand and mental states and events on the other: it is such acts or states and events that directly or indirectly provide the data for a grammar.
2. Grammars are to be formulated so as to account for language variability both within and between languages, i.e., they must presuppose a theory of linguistic variability.
3. They are formulated 'in terms of' a theory of language: a grammar includes terms, definitions, assumptions, and theorems from a theory of language that is presupposed in the grammar. These are used in the grammar (i) to provide descriptive terms for categories and other entities of the language under description, and (ii) to interact with terms, definitions, assumptions, and theorems that are specific to the grammar.

Typically, the axioms and theorems of a grammar of a language or language variety are formulated as universal implications over the systems of the idiolects in the given language or variety. For example, consider a traditional statement on a language variety, such as '*hack* "taxi" is a noun in Colloquial American English.' This is construed as equivalent to, 'For all *S*: If *S* is a system of some element of Colloquial American English, then ⟨*hack*, 'taxi'⟩ is an element of Noun-of-*S*,' which may be a sentence of a grammar that contains 'Colloquial American English' as an axiomatic constant, denoting a certain subset of English.

Generally, an integrational grammar is not an algorithm but a 'declarative' theory: its formulas have the form of statements; thus, the grammar's axioms and theorems can be understood directly as statements on the language, variety, or idiolect described by the grammar. Excepting the language needed for

formulating the semantic part of a grammar, integrational grammars may be formulated using an appropriate version of set theory. (For further details, see Lieb, 1983: sec. 0.2 and part G, and Lieb, 1993a: part V; for a critical evaluation of the Integrational Theory of Grammars from the perspective of the philosophy of science, see Falkenberg, 1996.)

Integrational Linguistics and Semiology

R Harris, Oxford University, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The term 'integrationism' is applied to an approach to language and communication originally developed by a group of linguists at the University of Oxford during the 1980s, and continued internationally since then. Historically, integrationism is sometimes regarded as an offshoot of Firthian linguistics (*see* **Firth, John Rupert (1890–1960)**), but that interpretation is contentious. An alternative is to see integrationist thinking as developing the view of language sketched in Wittgenstein's *Philosophical investigations* (*see* **Wittgenstein, Ludwig Josef Johann (1889–1951)**).

By 'integrational linguistics' is to be understood the application of integrationist principles to the study of language. The International Congress of Linguists included panel sessions on integrational linguistics at the 15th (Quebec 1992) and 16th (Paris 1997) world congresses. Publications which discuss integrationist approach in most detail are Davis and Taylor (1990); Toolan (1996); Harris (1996); Harris (1998); Harris and Wolf (1998); Davis (2001); and Davis and Taylor (2003). An International Association for the Integrational Study of Language and Communication was founded in 1998, and now has members in more than twenty-five countries. It holds biennial conferences (London 2000 on 'The Language Myth in the Western Tradition'; New Orleans 2002 on 'Language and History'; Birmingham 2004 on Language Teaching and Integrational Linguistics'). *Integrationist Notes and Papers* (2003–) publishes items of related interest.

Overview

Integrationism claims to offer a perspective on language and communication that differs radically from that adopted by mainstream schools of thought in linguistics and neighboring disciplines. Integrationists differentiate forms of communication according to the range of activities typically integrated by the participants, and by the kinds of integrational proficiency typically required for participation. From an integrationist perspective, the term 'language' does not correspond to any one mode of communication, but straddles or conflates several. For integrationists there is no clear-cut, universal distinction between the linguistic and the non-linguistic, or between 'knowledge of a language' and 'knowledge of the world.' (Integrationists sometimes refer to this as the 'principle of non-compartmentalization.') On this fundamental issue, integrationists stand at the opposite end of the theoretical spectrum from mainstream work in linguistics of the 20th century (as exemplified by Saussure, Bloomfield, Chomsky, and many others). Integrationists propose a linguistics that is 'lay-oriented'; that is, deriving its basic concepts from the first-order communicational experience of lay members of the community.

Thus, for integrationists, the analysis of communication at all levels has to take into account three types of factor: biomechanical, macrosocial, and circumstantial. Integrationists reject abstractions such as 'grammatical rules,' invariant 'lexical items,' and the rest of the metaphysical apparatus that sustains all current versions of 'autonomous' linguistics (*see* **Autonomy**). Autonomous linguistics, at least as defined in Newmeyer (1986), is virtually co-extensive with what integrationists call 'orthodox' modern linguistics. According to Newmeyer, Saussure was the theorist who formulated "the classic statement" of the autonomy of synchronic linguistics, while Chomsky was "the world's leading exponent of autonomous linguistics."

This rejection of orthodox/autonomous linguistics reflects the integrationist tenet that communication cannot be decontextualized. There is no question of distinguishing between the study of 'languages' and the study of their 'use,' because this already presupposes an *a priori* dichotomy between the user and the system to be used. For integrationists, human beings are not language-users but language-makers (Harris, 1980): they are constantly making and remaking language as they go. They do this by exercising and extending their integrational proficiency in all forms of communication available to them. It is this creative faculty which holds the key to human linguistic achievements. The linguistic sign has as its basic function in communication the integration of past, present, and (anticipated) future experience, giving rise to what integrationists call the 'principle of cotemporality.' This principle obliges the linguist to recognize that one of the fundamental characteristics of the sign is its location in time.

Approaches which, on the contrary, assume the validity of treating languages as static 'codes' existing independently of their 'uses' and 'users' are criticized by integrationists as being 'segregationist.' A segregationist approach is the foundation of traditional grammar in Western education, from Dionysius Thrax onwards. Segregationism is also the main charge integrationists level against orthodox

modern linguistics. Segregationism insists on boundaries where in practice there are none. It misrepresents – in the integrationist's view – the relationship between language and communication, and in so doing misrepresents language. The integrationist denies that there are any 'autonomous' systems of linguistic signs of the kind that orthodox theorists assume. This leads to what is perhaps the most controversial claim associated with integrationist thinking: that 'languages' do not exist (On 'linguistics without languages,' see Joseph, Love and Taylor, 2001). In other words, languages, for the integrationist, are not part of anyone's first-order linguistic experience, but metalinguistic constructs serving a variety of ideological purposes.

Integrational Semiology

Integrationism treats communication as being invariably mediated by signs of some kind. It makes strong assumptions about the semiological conditions under which communication is possible. But it rejects the orthodox 'sender–receiver' model, whereby discrete 'messages' are passed along a line or channel of transmission from one individual to another.

Integrationism also makes very strong assumptions about the capacities required of an individual in order to engage in communication. These divide into 'biomechanical,' 'macrosocial,' and 'circumstantial' capacities. The first relates to the human organism and the human ability to integrate a wide variety of physiological and mental activities. (For example, the very diverse biomechanical requirements for phonation and audition: deafness interferes with communication in quite different ways from speech impediments.) The macrosocial dimension relates to the ability to integrate particular activities into a general framework provided by social conventions of various kinds, ranging from religious ritual to traffic regulations. The circumstantial factor relates to the ability to integrate one's activities into whatever conditions may obtain at the time. These three sets of parameters are regarded by integrationists as the foundational infrastructure of all human communication, of whatever modality.

From all this it follows that the integrationist conception of the sign is to be distinguished from at least the following.

1. The sign conceived of as a physical object of some kind. (Thus the motorist's warning triangle is not a sign when lying in the boot of the car.)
2. The sign conceived of as an abstraction underlying and giving meaning to physical objects (as in the Highway Code, where we are given explanations of how to interpret certain visual configurations that appear on public notices erected by local authorities).
3. The sign conceived of as a psychological unit linking a form and a meaning (e.g., as proposed by Saussure, a mental association between a certain sound-image and its corresponding concept).
4. The sign conceived of in Peircean terms of types and tokens. (The integrationist sign is neither a type nor a token. Words, as listed and defined in dictionaries, are not linguistic signs but metalinguistic abstractions.)

All this carries over to visual and other forms of communication. Thus, for instance, neither the physical object which exists uniquely as Michelangelo's statue *David*, nor anyone's public or private image of that statue, nor any collective representation or reproduction of the corresponding images, qualify as examples of an integrational sign. The sign is not to be equated with the original exemplar or any extrapolation therefrom. It exists as a construct by reference to which certain communicational activities (pointing to the statue, or photographs of it, or talking about the statue, or referring to what other people have said or written about the work of Michelangelo, in some particular instance) are integrated. Apart from such integrational activities, the sign as such has no existence. The 'name' of the work (*David*) is subject to exactly the same conditions of communication. It goes without saying that signs do not depend on having some 'real object' as what they 'stand for,' or any 'real person,' whom Michelangelo might have believed he was depicting.

For integrationists the linguistic sign, like all other signs, is a product of contextualization, resulting from and facilitating the integration of particular activities in particular circumstances. Thus, for instance, looking up a word in a dictionary is not a process of discovering or verifying the given facts about a given sign whose existence is independently guaranteed by God, or Nature, or Society (or even the academic consensus of lexicographers). Far from it. For obvious reasons, therefore, integrational semiology is anathema in orthodox linguistics, which is based from start to finish on the hypostatization of units such as 'word,' 'phrase,' 'sentence,' etc. taken over from traditional grammar.

At the most general level, the axioms of integrational semiology may be stated as follows:

1. What constitutes a sign is not given independently of the situation in which it occurs or of its material manifestation in that situation.
2. The value of a sign (i.e., its signification) is a function of the integrational proficiency which its identification and interpretation presuppose.

Under the principle of cotemporality, a sign can never be repeated. It can only be reintegrated into the communication process by the production of a subsequent sign. Integrational proficiency is accordingly construed not as a 'competence' in the sense of orthodox linguistics, but as a situated ability to deploy the biomechanical, macrosocial and circumstantial skills required in a particular communication situation. Thus, for the integrationist, there is no such achievement as 'integrational proficiency in English' (or any other language), even though in a particular case familiarity with certain English words might be one of the macrosocial factors involved in the process of communication. Likewise, there is no level at which the individual can be treated semiologically as just a stereotypical – or deviant – 'speaker of language *X*,' or 'musician of school *Y*.' There are no 'completely homogeneous communities' of the kind appealed to by some linguistic theorists. (The point is not just that they cannot be found in the 'real world,' but that their postulation is theoretically incoherent.) The individual is always unique and exploits that uniqueness semiologically as participant in a series of open-ended communication situations.

The Language Myth

For integrationists, the traditional Western notion of languages as spoken or written systems corresponding to such names as 'English,' 'Latin,' or 'French' answers to nothing in first-order experience and in any case falls foul of the theoretical maxim known as 'Occam's Razor.' It is therefore discarded. There is no theoretical need for such systems to be postulated as occupying an intermediate position between language (as a human 'faculty') and speech or writing (as human activities). The conviction that such intermediate entities 'really exist,' or are at least necessary fictions for purposes of linguistics, is referred to by integrationists as 'the language myth' (Harris, 1981; Harris, 2002; Farrow, 2005).

The language myth has a long history that goes back to Classical antiquity and has become enshrined in most European education systems. It was encouraged politically by the rise of the nation-state with its ideal of 'one country–one language' and the foundation of national language academies. The emergence of modern linguistics as an academic discipline was strongly influenced by these sociopolitical ideologies (Hutton, 2002). Language-teaching today is criticized by integrationists as one of the most powerful agencies which continue to propagate the language myth to new generations. The analysis of this myth and its implications is therefore seen as an essential first step towards the goal of 'demythologizing' linguistics.

In rejecting the language myth, integrationists reject the orthodox view that language is 'rule-governed.' They see human communication as an unregulated continuum embracing both verbal and nonverbal signs. In its canonical versions, the language myth is based on two ancient fallacies about communication. These, although logically independent, lend each other powerful support. One is the assumption that speech is a form of 'telementation,' a means of conveying thoughts from one individual mind to another individual mind. Its twin thesis is that effective communication through speech or writing requires a fixed code into which thoughts can be 'encoded' for transmission. (This second thesis is sometimes referred to by integrationists as the fallacy of 'linguistic determinacy.') The fallacy of telementation and the fixed-code fallacy are seen as being mutually complementary in the following sense. Telementation provides an (alleged) explanation of how fixed codes function and what they are for; while fixed codes in turn provide an explanation of how telementation is possible. But this simplistic binary structure of interdependence is itself mythical. In practice, interpersonal communication is a creative, multidimensional form of contact between individuals, but operating in conditions that individuals do not necessarily control. Nor, even if they do, are they necessarily aware of the communicational implications.

Integrationists trace the language myth back in various forms from early generative grammar to Saussure, from Saussure back to Locke and Port-Royal, and thence via medieval modistic grammar to Aristotle. The language myth still provides the framework, often unacknowledged, or even unrecognized (Farrow, 2005), for most segregationist accounts of linguistic structure. Integrationists accordingly regard the 'demythologization' of contemporary linguistics as an important objective.

As integrationists have pointed out, the language myth plays a considerable role in contemporary social institutions: for example, in the law (Sinsheimer, 2005). Recent work has addressed the more general question of how society's macrosocial supercategories (such as art, history, science) are semiologically constructed (Harris, 2003; Harris, 2004; Harris, 2005). In these respects integrational linguistics goes far beyond the narrow scope recognized by proponents of linguistic orthodoxy.

'Standard' Languages and Dialects

A key component in the program of demythologization concerns the widespread belief (both among academics and the general public) in so-called 'standard' languages. These hypothesized public codes are among the mythical objects allegedly described by

orthodox grammarians and lexicographers. They are often set up as approved codes to be taught to foreign learners. The usages identified as standard are those from which deviation is rejected as 'incorrect.' Despite claims to the contrary, the whole notion of a standard language, as propagated in modern linguistics and associated educational programs, is intrinsically prescriptive. In rejecting it, together with its social and political implications, integrationists have pointed out the complete failure by linguists to identify any objective set of criteria by which a standard language might in practice be unambiguously identified. This is not only because linguistic usage is constantly changing, both quantitatively and qualitatively, but because the problem of identifying the membership of a language community, and specifying qualifications for membership, is theoretically intractable.

The notions 'standard' and 'dialect' are head and tail of the same segregationist coin. The result of this spurious opposition is that many teachers are encouraged to treat 'dialect' as the equivalent of 'nonstandard' or ('substandard'), since 'standard' automatically carries implications of superiority in one respect or another. Integrationists point out that the function of the opposition of 'standard versus dialect' in segregationist thinking is actually to solve a theoretical as well as a pedagogic dilemma; namely, how to reconcile the manifest fact of linguistic diversity between speakers with the need to identify a determinate code to which the linguist's analytic procedures may be applied. When orthodox linguists are challenged on this score, they resort to a multiplication of standards. Thus 'standard English' proliferates into 'standard American English,' 'standard Scottish English,' 'standard Welsh English,' and even 'standard English English.' The fact that there is no limit in principle to this multiplication of standards demonstrates, for integrationists, the absurdity of the concept.

Speech and Writing

One main thrust of integrationist work has been to demythologize the important relationship between speech and writing, which has had a pervasive effect on thinking about language in the Western tradition (*see* **Western Linguistic Thought Before 1800**). Misconceptions about this relationship are endemic in literate societies. Integrationists point out the inadequacy of treating writing as just a conventionalized transcription of speech. A comprehensive integrational analysis has been proposed for the various forms of writing (Harris, 1995). It starts from the assumption that, since the biomechanical, macrosocial, and circumstantial requirements for written communication are quite different from those for spoken communication, there is no way that one can be regarded as an alternative implementation of the other. The widespread notion that writing contrasts with speech as 'visual' communication versus 'oral' communication is also taken to be mistaken. Writing, viewed from an integrationist perspective, turns out to be a more powerful and flexible form of communication than speech could ever be.

Conclusion

The prospects for any reconciliation between integrationist thinking and orthodox linguistics seem remote, given the wide difference between them in epistemological assumptions. If integrationists are right, much of what passes for linguistic structure in the orthodox view is actually no more than an artifact of the codification procedures employed to 'describe' it. Whether orthodox theorists can offer any effective rebuttal of this fundamental critique remains to be seen.

Intensifiers

E König, Free University of Berlin, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Terminology

The term *intensifier* is here used for expressions such as English *him-/herself*, for Latin *ipse*, Italian *stesso*, Russian *sam*, Mandarin *ziji*, German *selbst*, etc., and their counterparts in other languages. There is no generally established label for these expressions and most of the terms used, such as *emphatic reflexives*, *emphatics*, *pronouns of identity*, *particles*, *scalar adverbs*, etc., are highly misleading even for individual languages, to say nothing of cross-linguistic studies. The term *intensifier*, first used in Moravcsik (1972) and Edmondson and Plank (1978), has the advantage of being more or less free of such misleading connotations, though it is also sometimes used for adverbs of degree such as *very* or *extremely*.

Intensifiers such as the ones listed above are most easily identified across languages in terms of their prosodic and their semantic properties. They are invariably focused and thus stressed. Another reasonably general property seems to be the fact that they are used as adjuncts rather than arguments within a sentence. As far as their other morphosyntactic properties are concerned, they may differ quite strikingly from language to language. In those cases in which their etymology can be established beyond reasonable doubt, we also can say that they typically derive from expressions for body parts ('head', 'heart', 'body', 'bone', 'eye', but also 'soul' and 'mask'). This etymology is still visible in Semitic, Indic, Caucasian, and many African languages, as well as in creoles (cf. Heine, 2000, 2003).

A further characterization of intensifiers is possible if one examines their typical uses. Four different use types can be distinguished, not all of which are found in each language, however. The following four uses can be found in a wide variety of languages, but there are many languages that have only the first two. The third use type seems to be the rarest of the four and the fourth use is often associated with a specific form that is differentiated from the other uses. The following English examples provide an instance of each use:

(a) the adnominal use

(1) Writers themselves, rather than their works, should be examined for their sense of social responsibility.

(b) the adverbial exclusive use (≅ 'alone')

(2) Mrs. Dalloway wanted to buy the flowers herself.

(c) the adverbial inclusive use (≅ 'too')

(3) If he's busy breaking the rules himself, he could hardly demand that they do otherwise.

(d) the attributive/possessive use

(4) This is a matter between you and your own conscience.

In English, as in many other European languages, the same intensifier (X-*self*) can be used in three different contexts and with three different interpretations. In its adnominal use X-*self* is adjoined to the right of an NP (or DP) and exhibits agreement with that constituent. The adverbial use also exhibits agreement with a nominal constituent, although the intensifier is not adjacent to that constituent but in construction with a VP or a projection thereof (cf. (2)–(3)). The two adverbial uses are primarily differentiated on the basis of their meaning and because there is a certain complementarity between these uses, they may well be the result of contextual factors interacting with one univocal adverbial

Intensifiers

E König, Free University of Berlin, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Terminology

The term *intensifier* is here used for expressions such as English *him-/herself*, for Latin *ipse*, Italian *stesso*, Russian *sam*, Mandarin *ziji*, German *selbst*, etc., and their counterparts in other languages. There is no generally established label for these expressions and most of the terms used, such as *emphatic reflexives*, *emphatics*, *pronouns of identity*, *particles*, *scalar adverbs*, etc., are highly misleading even for individual languages, to say nothing of cross-linguistic studies. The term *intensifier*, first used in Moravcsik (1972) and Edmondson and Plank (1978), has the advantage of being more or less free of such misleading connotations, though it is also sometimes used for adverbs of degree such as *very* or *extremely*.

Intensifiers such as the ones listed above are most easily identified across languages in terms of their prosodic and their semantic properties. They are invariably focused and thus stressed. Another reasonably general property seems to be the fact that they are used as adjuncts rather than arguments within a sentence. As far as their other morphosyntactic properties are concerned, they may differ quite strikingly from language to language. In those cases in which their etymology can be established beyond reasonable doubt, we also can say that they typically derive from expressions for body parts ('head', 'heart', 'body', 'bone', 'eye', but also 'soul' and 'mask'). This etymology is still visible in Semitic, Indic, Caucasian, and many African languages, as well as in creoles (cf. Heine, 2000, 2003).

A further characterization of intensifiers is possible if one examines their typical uses. Four different use types can be distinguished, not all of which are found in each language, however. The following four uses can be found in a wide variety of languages, but there are many languages that have only the first two. The third use type seems to be the rarest of the four and the fourth use is often associated with a specific form that is differentiated from the other uses. The following English examples provide an instance of each use:

(a) the adnominal use

(1) Writers themselves, rather than their works, should be examined for their sense of social responsibility.

(b) the adverbial exclusive use (≅ 'alone')

(2) Mrs. Dalloway wanted to buy the flowers herself.

(c) the adverbial inclusive use (≅ 'too')

(3) If he's busy breaking the rules himself, he could hardly demand that they do otherwise.

(d) the attributive/possessive use

(4) This is a matter between you and your own conscience.

In English, as in many other European languages, the same intensifier (X-*self*) can be used in three different contexts and with three different interpretations. In its adnominal use X-*self* is adjoined to the right of an NP (or DP) and exhibits agreement with that constituent. The adverbial use also exhibits agreement with a nominal constituent, although the intensifier is not adjacent to that constituent but in construction with a VP or a projection thereof (cf. (2)–(3)). The two adverbial uses are primarily differentiated on the basis of their meaning and because there is a certain complementarity between these uses, they may well be the result of contextual factors interacting with one univocal adverbial

intensifier. In attributive (possessive) contexts, Modern English uses a special intensifier (*own*), but as late as the 17th century the intensifier *self* could still be used in such contexts.

(5) . . . and syddan hit his discip(ul)um sealde to þicganne for his sylfes lichaman and for his agan blod. '. . . and then gave it to his disciples to take and eat as if it were his own body and his own blood.' (Wulfstan Pol 3 (Jos) 17)

In other words, *own* fills a gap in the distribution of X-*self* in Modern English in contrast to earlier forms of that language or languages like Turkish, where the same expression (*kendi*) is found in the adnominal, adverbial, and attributive functions (*kendi odam* 'my own room'). In addition to these four uses, further uses of the same expressions with different though related meanings can be found in many languages (e.g., German *Selbst der Chef* 'Even the boss,' d*erselbe Verbrecher* 'the selfsame criminal,' etc.).

As far as their morphology and distribution are concerned, intensifiers have special properties and cannot be subsumed under any of the established lexical (or functional) categories. In a large number of languages they inflect for the morphosyntactic features typically associated with nouns or pronouns (number, gender, person, case) and the fact that they invariably agree with a noun or noun phrase suggests that they should be analyzed as a specific subclass of adjectives. Such an analysis is particularly tempting in those cases where intensifiers precede rather than follow an adjacent noun, as in the case of Spanish *mismo*, Italian *proprio*, Zapotec *lagakh* or English *own*. In an equally wide variety of languages, intensifiers are invariant particles and manifest a partial overlap in their distribution with focus particles like 'alone,' 'too,' 'only,' 'even.' Moreover, the versatility in their syntax, illustrated by the examples (1)–(4), is also similar to the distribution of focus particles. Semantically and prosodically, however, they differ strikingly from both adjectives and focus particles. As pointed out above, intensifiers are invariably stressed and thus focused, rather than being merely associated with a focus (like focus particles) or stressed under specific contrastive conditions (like adjectives). This striking prosodic property is closely linked to, and in fact a consequence of, their meaning. As pointed out in Eckardt (2002) and Hole (2002), intensifiers can simply be analyzed as denoting the identity function and thus would make a completely trivial contribution to the meaning of a sentence if they were not focused. Under stress and focus these expressions denote functions that map the value denoted by their nominal co-constituent onto alternative values, i.e. entities defined in terms of the value given. Applied to a preceding noun phrase like *writers* in (1), the intensifier simply leads to the very same semantic value as the noun phrase alone (i.e., 'writers'). The effect of the focus and stress on *himself*, however, is that the denotation of *writers* is mapped onto alternative values, i.e., values definable in terms of this expression (e.g., 'their families,' 'their ideas,' 'their works,' etc.). In (1), the third of these possible alternatives is in fact the alternative envisaged by the speaker and explicitly given in the context. More often than not such alternatives can also be described as 'entourage, periphery' of the value denoted by the co-constituent taken as the center (cf. König, 1991). These characteristic prosodic and semantic properties strongly argue for assigning intensifiers to a class of their own.

Parameters of Variation

Intensifiers may differ strikingly in their formal, distributional, and selectional properties across languages, but they do so quite systematically and within very clear limits.

Agreement vs. Invariance

One of the most striking parameters concerns their morphological makeup: Intensifiers may agree with their co-constituents in terms of morphological features typically associated with nouns (the so-called φ-features) or simply be invariant (particles). Examples of invariant, particle-like intensifiers are found *inter alia* in Albanian, Bambara, Modern Breton, and all Germanic languages other than English.

German

(6) [Sie *selbst*] hat es mir gesagt.
she-INT has it- 1SG.-DAT said
'She herself told me about it.'

In the other languages, by contrast, intensifiers inflect for some of the φ-features mentioned above (gender, number, person, case), thus manifesting agreement with the nominal constituent to which they relate syntactically and with which they interact semantically (their 'co-constituent'). The set of languages that manifest such agreement includes English, the Romance languages, the Finno-Ugric, and the Turkic languages:

Finnish

(7) Saa-n-ko puhua johtaja-lle
may-1SGPRES-Q speak director-ALL
itse-lle-en
INT-ALL-3POSS
'Could I talk to the director himself?'

Relation to Reflexive Anaphors

Intensifiers play an important role in the genesis, reinforcement and renovation of reflexive anaphors (cf. König and Siemund, 2000; König, 2003), and one of the most interesting parameters of variation therefore concerns their relationship to reflexive anaphors. Three options can be distinguished among the languages of the world: (a) intensifiers and reflexives are identical in their formal properties and only differ in their distribution, reflexive anaphors occurring in argument position and intensifiers in adjunct positions; (b) intensifiers and reflexives are formally differentiated, differing thus in both their form and their distribution; and (c) intensifiers and reflexives share morphological material or are at least similar in their formal properties, though not in their distribution.

Complete formal identity between intensifiers and reflexives is found in all of the following languages: English, Mandarin, Finno-Ugric, most Caucasian, Indian, Semitic, and Turkic languages. In grammars of these languages intensifiers are often categorized as emphatic reflexives and discussed in the same chapter or section as reflexives (e.g. Huddleston and Pullum, 2002: 1483–1498).

(8a) The bride herself remained calm throughout the ceremony.
(8b) The bride is looking at herself in the mirror.

In languages of the second group (b), intensifiers and reflexive markers are clearly distinct and are never discussed under the same heading in the relevant grammars. Examples from French exemplify an equally widespread situation among the languages of the world:

French

(9a) Pierre se déteste.
'Peter hates himself.'
(9b) Pierre lui-même va nous adresser la parole.
'Peter himself will talk to us.'

Reflexive markers in such languages are generally highly grammaticalized instances of the pronominal strategy for marking reflexivity (cf. Faltz, 1985) and are also typically employed as middle markers (i.e., markers of derived intransitivity) in anticausative, modal passive, and reciprocal constructions (cf. Kemmer, 1993).

The third type identified by the parameter of variation under discussion includes all those cases where intensifiers and reflexive markers share some morphological material without being formally identical. The typical situation here is that the reflexive marker is analysable as intensifier + some additional morpheme, e.g., a personal pronoun or reflexive pronoun. This type thus also includes Dutch and the Scandinavian languages, in which a reinforcement of the basic reflexive pronoun (*zich*, *sig*) by the intensifier has been grammaticalized for all stereotypically other-directed predicates.

Selectional Restrictions

The following parameter of variation makes intensifiers very different from focus particles, but is not all that surprising in view of the adjective-like inflectional behavior exhibited by these expressions in many languages: intensifiers may or may not exhibit selectional restrictions with regard to the nominal constituents they interact with. It is, however, not the language as a whole that imposes specific restrictions but specific intensifiers in individual languages. Examples of intensifiers with no, or at least almost no, combinatorial restrictions are German *selbst*, Spanish *mismo* and Amharic *–ras-*. A differentiation quite frequently found among the distribution of intensifiers relates to the opposition between animate and inanimate nouns. In Japanese *zisin* is only used with animate nouns, whereas *zitai* is used with inanimate nouns:

Japanese

(10a) *Taroo-zisin* *kyouzyu-o* *sonkeisiteiru.*
Taro-self professor-ACC honours
'Taro himself honours the professor.'

(10b) *Kono hon-zitai* /*zisin *yomunoga* *muzukasii.*
this book-self to.read difficult.is
'This book itself is difficult to read.'

Other frequent differentiations relate to the distinction between local, temporal, and abstract nouns vs. the rest (e.g., French *même* vs. *lui*-même, *elle-même*) and to person distinctions (1st and 2nd person vs. 3rd person in Basque), so that the relevant selectional restrictions are describable in terms of the well-known Animacy Hierarchy.

Intention and Semantics

S Barker, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

A compelling idea is that words have meanings because speakers who use them have intentions of some kind. Intentions underpin semantics. One proposal of how this might work is based on Locke's idea (1975) that the function of a language is to express preexisting thoughts; thoughts are correlated with sentences through intentions. So intentions are the glue binding thoughts to words.

Grice (1958, 1969) adopts this Lockean view. Grice divides verbal meaning into two kinds: so called 'speaker-meaning' and 'sentence-meaning.' Speaker-meanings are the contents of particular utterances on occasions. They are the contents of illocutionary acts (in the sense of Austin, 1962) performed by production of sentences. Illocutionary acts include assertions, orders, questions, etc. Speaker-meanings may diverge from sentence-meanings, which are literal meanings. U may employ 'The church is a rock' but convey as speaker-meaning that the church is a strong support for its members; U may utter 'The meal is edible,' conveying as speaker-meaning that it is not very good.

Grice begins his analysis of meaning by examining the intentions underpinning speaker-meaning. Grice takes the intentions that do the job to be communicative intentions. A communicative intention is social: it is directed toward an audience. In communication – speaking-meaning something – a subject U intends that her audience H gain a certain state *r*, a belief, desire, intention, etc. Grice's great insight was into the structure of the communicative intention, which he characterized thus:

> **C**: U means something by utterance *S* if and only if U utters *S* and intends that H acquire characteristic *r* and U intends that H do so partly by recognizing this very intention.

The intention is a **reflexive intention**: an intention that falls within its own scope. Many philosophers have been wary of the reflexive treatment of communication and have attempted to explicate communicative intentions in terms of hierarchies of intentions. See Grice (1969), Strawson (1964), and Schiffer (1972). But the results are unwieldy.

One proposal of how this might work is based on Locke's idea (1975) that the function of a language is to express preexisting thoughts; thoughts are correlated with sentences through intentions. So intentions are the glue binding thoughts to words.

Grice (1958, 1969) adopts this Lockean view. Grice divides verbal meaning into two kinds: so called 'speaker-meaning' and 'sentence-meaning.' Speaker-meanings are the contents of particular utterances on occasions. They are the contents of illocutionary acts (in the sense of Austin, 1962) performed by production of sentences. Illocutionary acts include assertions, orders, questions, etc. Speaker-meanings may diverge from sentence-meanings, which are literal meanings. U may employ 'The church is a rock' but convey as speaker-meaning that the church is a strong support for its members; U may utter 'The meal is edible,' conveying as speaker-meaning that it is not very good.

Grice begins his analysis of meaning by examining the intentions underpinning speaker-meaning. Grice takes the intentions that do the job to be communicative intentions. A communicative intention is social: it is directed toward an audience. In communication – speaking-meaning something – a subject U intends that her audience H gain a certain state *r*, a belief, desire, intention, etc. Grice's great insight was into the structure of the communicative intention, which he characterized thus:

> **C**: U means something by utterance *S* if and only if U utters *S* and intends that H acquire characteristic *r* and U intends that H do so partly by recognizing this very intention.

The intention is a **reflexive intention**: an intention that falls within its own scope. Many philosophers have been wary of the reflexive treatment of communication and have attempted to explicate communicative intentions in terms of hierarchies of intentions. See Grice (1969), Strawson (1964), and Schiffer (1972). But the results are unwieldy.

Speaker-meanings are, then, acts with the form **C**. The different types of speaker-meanings or illocutionary acts, that is, assertions and orders etc., are determined by the different characteristics *r* intended. Grice (1971: 123) analyzes assertions and orders thus:

> **GA**: U asserts (to H) that P by uttering *S* iff U utters *S* reflexively intending that H believe that U believes that P.
> **GO**: U orders (H) to do F by uttering *S* iff U utters *S* reflexively intending that H form an intention to F.

Such proposals about *r* are problematic, however. Restricting ourselves to assertion, **GA** is refuted by apparent cases in which U lacks an intention that H believe that P – e.g., where U either *(a)* is indifferent as to H's belief, because, for example, U is engaged in polite conversation without intending to persuade; or *(b)* believes H won't believe her. (See Alston, 2000). Bach and Harnish (1979), suggest the primary intention should rather be:

> that H has a reason to believe that U believes that P.

If, as suggests Recanati (1986), reasons are defeasible, then U can provide a reason for H to believe P, even though U knows it is undermined by further information, such as that H believes U is a liar.

Assuming that some such explication of *r* works, how can we use speaker-meaning to analyze sentence-meaning? Grice (1971) introduces practices and conventions thus:

> **SM1**: *S* means that *P* for U iff U has the practice that if she desires to reflexively intend that H gain *r*, then she (may) utter *S*.

The 'may' here can be taken as rule permissibility or epistemic 'may.' **SM1** allows words to be ambiguous, and for there to be different ways of saying the same thing. Grice notes that the regularity governing use of the sentence *S* does not itself have to be one that correlates use of *S* with full-fledged reflexive intentions. Rather we simply need:

> **SM2**: *S* means that *P* for U iff U has the practice that if she desires to intend that H gain *r*, then she (may) utter *S*.

If the conventions/practices governing sentences have this form, we can then explain how speaker-meanings – full illocutionary acts – emerge in particular utterance events. In uttering *S*, U intends H to think thus:

> U's policy is that if U intends that H have *r*, then U (may) utter *S*.
> U uttered *S*, so (given context) I can infer that U intends that H have *r*.
> U intends that H have *r*.
> So, I should have *r*.

Thus, U is intending that H have *r*, partly in virtue of recognizing U's intention that she have *r*. But this is just reflexively intending that H have *r*.

To analyze word-meaning we need regularities such as:

> **WM**: The word Ω means *O* for U iff U has the practice that if U desires that H believe U believes something about *O*, then U (may) utter a sentence . . .Ω . . . .

Given that U has such dispositions for the basic vocabulary of her language, we can deduce the kinds of dispositions that will underpin her production of novel (unuttered) sentences. We provide thereby a compositional account of the meaning of sentences in U's language.

Platts (1979: 86–94) doubts this last point. He thinks the very thing we are meant to be explicating, sentence-meaning, will have to be brought in to fix the intentions that U would have if she were to use novel sentences. Blackburn (1984: 127–129) objects that it is just the practices and dispositions themselves that fix what we would intend, and thus mean. Nothing else need back up such dispositions.

A more serious objection to the Gricean account of meaning is that repertoire rules for the words require us to appeal to the semantic relation of **aboutness**. **WM** invokes U's believing something **about** object *O*. Aboutness is related to denotation, that is, a representational relation between mental state or word and world. But meanings, one might think, are simply representations. So, as Devitt and Sterelny (1999: 150–151) point out, the Gricean analysis effectively leaves unexplained the realm of content as such. Perhaps we need a Fodorean (1975) language of thought hypothesis to finish the story. Or perhaps there is some way of giving a pragmatic reduction of representation in terms of an inferential semantics (Brandom, 1994). Or we should see Grice's analysis of speaker-meaning and its relation to sentence-meaning as merely providing an explanation of what it is for particular speakers to use one language – whose representational contents are abstractly defined in terms of truth-conditions – rather than another (Lewis, 1975). If so, as Blackburn (1984: 134) points out, there is no rivalry between intention-based semantics and formal truth-conditional approaches, *contra* Strawson (1964).

Or there is this possibility. An intention-based semantics might change tack by denying that meanings, *qua* semantic interpretations, are representations as such. This approach is found in Barker (2004). It contends that the semantic interpretations of words and sentences are not representational contents but speech act types – acts whose nature is not merely representational. These speech acts are a specific kind

called 'proto-speech-acts.' A proto-act is uttering a word, phrase, or sentence and **advertising** certain intentions to denote, represent, or communicate. Advertising is engaging in the behavior characteristic of a speaker who, following certain rules, intends to do something. In uttering a name, for example *Pegasus*, U utters a term, *Pegasus*, and advertises an intention to denote an object, something called *Pegasus*. If U utters 'I saw Pegasus,' she wants H to believe she has the intention she advertises, but if she asserts 'Pegasus does not exist,' she does not. What defines a name's meaning is not any object denoted, since like *Pegasus* it might be empty, but the proto-referring act associated with it. The meaning of *Pegasus* is that proto-referring act all of whose tokens are nodes of a certain referential tree: that subset of uses of the name *Pegasus* that we group together as instances of the name for the mythical flying horse.

The meaning of a declarative sentence is a 'proto-assertion.' A proto-assertion involves two parts: advertising *(a)* a representational intention and *(b)* a communicative intention. In uttering 'Snow is white,' U advertises intentions *(a)* to represent that snow is white, and *(b)* to **defend** the intention to represent snow's whiteness. Defending is dialectical engagement with an audience H: in defending an intention to represent that snow is white, one wants H to accept or reject such an intention in her own case, and to give reasons for rejection. H judges correct an **assertion** of 'Snow is white' – where U really does intend to defend an intention to represent that snow is white – iff H accepts what U defends.

Assertion of 'Snow is white' is a **report**, since what is defended is a representational intention. But not all assertions are reports. Utterance of 'Haggis is tasty' is an expression of taste: U advertises intentions to *(a)* represent her possession of a gustatory preference state of liking haggis, and to *(b)* defend that gustatory preference state. Preference states are not representational. H judges correct U's assertion iff H accepts the gustatory preference state in her own case; not if and only if H thinks U has represented correctly her, U's, state.

In this framework, all logically complex sentences have expressive proto-assertions as their meanings. Negations express rejective states. In uttering 'Snow is not white,' U advertises intentions to *(a)* represent that she has a rejective state with respect to intending to represent snow is white, and to *(b)* defend that rejective state. In uttering 'Haggis is not tasty,' U expresses rejection of the gustatory property. And so on for other logically complex sentences. Statements of the form '*S* is true' are expressive as well; U expresses her acceptance of the state defended in assertion of *S*. Because sentence-meanings are not representations, we are not committed to logically complex entities in the world, such as negative or universal facts, or mysterious properties of truth.

A compositional semantics can be built through constructing meanings in terms of proto-acts, proto-referrings, and proto-assertions. Proto-assertions, for example, can embed in logical compounds. In 'either *S* or *R*,' *S* and *R* are proto-asserted. Hence **advertising** intentions is weaker than the condition articulated above of giving a defeasible reason to believe.

This approach does not attempt to explicate representation in speech act terms. Rather, it displaces representation as the keystone of meaning. Names and sentences don't have to denote/represent to be meaningful. Truth-bearers are not propositions, *qua* representational contents, but assertions: acts of defending states. This account does not tell us what denotation and representation are, but, unlike the Gricean approach, it is not committed to saying that meaning resides in such relations holding. The result is an intention-based semantics that seriously challenges the dominant truth-conditional approach to meaning.

Interactional Sociolinguistics

'Interactional sociolinguistics' (IS) can be described as the application of interpretive methods of discourse analysis to gain detailed insights into the many communicative issues that arise in today's social environments, by means of systematic investigation of how speakers and listeners involved in such issues talk about them in the conduct of their affairs. This description is couched in general terms and includes a minimum of technical terminology, but it builds on premises that need to be spelled out in more detail. For instance, the notion of 'discourse' has become widely used in the general academic literature, with such expressions as the 'discourse(s)' of science, of mathematics, or of psychiatry. These terms often replace established categorizations for disciplines or specialist activities as a way of focusing on what practitioners do rather than relying on established nominal labels.

'Formal linguists' are concerned with the grammatical rules of specific languages and dialects and look at discourse as a string of utterances that can be reduced to the grammar and lexicon of constituent sentences and analyzed by established analytical procedures. 'Sociolinguists,' on the other hand, deal with the talk of individuals speaking as members of specific groups and engaging in context-bound encounters where, along with grammar and lexicon, social and cultural forces constrain both what can be said and how it can be said. It follows that to participate in an encounter requires both linguistic and social knowledge.

But how does language interact with the social? Earlier sociolinguistic investigations turned to the published ethnographic literature for social information. In today's complex and rapidly changing societies, however, established social science concepts such as class, gender, and ethnic group cannot account for the ever-increasing diversity of the social ecologies in which we live. Social knowledge is increasingly seen as constructed through interaction. Discursive practice, the argument goes, rests on interaction, requiring the active participation of speakers and listeners, who use knowledge of the entire semiotic situation – of which speaking is a part – along with their linguistic knowledge to understand what is intended at any one point.

Theoretical Roots

A main motivation for interactional linguistic research is the search for replicable qualitative methods of sociolinguistic analysis that can provide insights into the inherent linguistic and cultural diversity that characterizes current communicative environments. These methods are also used to document the impact of the diverse environments on members' everyday lives without relying on traditional social science categorizations. It is by now evident that diversity can no longer be treated as primarily a matter of distinctions among bounded, locally homogeneous language/culture units. Regardless of where we live, diversity is all around us. A large and ever-growing number of empirical sociolinguistic studies testify to its extent and significance, even in areas and domains of activity traditionally considered to be monolingual and monocultural. Questions of diversity loom large in public debates and in the recent social science writings that have greatly transformed our current thinking about social and cultural phenomena. Yet so far most attempts to deal with the communicative import of diversity, particularly its role in everyday communication, continue to rely on essentialized, taken-for-granted notions of culture and group on the one hand and dialect, style, or speech variety on the other. Such attempts to explain what happens in talk in terms of extra-communicative notions, whose relationship to real-life discursive practices is highly questionable, are unlikely to yield replicable results.

The 1960s writings on 'ethnography of communication' (EC) in a sense laid the foundation for current IS research. In his well-known 1960s critique of post–World War II Whorfian studies, Hymes (1962) argued that the failure of current research to provide empirical validation of relations between linguistic and

'Interactional sociolinguistics' (IS) can be described as the application of interpretive methods of discourse analysis to gain detailed insights into the many communicative issues that arise in today's social environments, by means of systematic investigation of how speakers and listeners involved in such issues talk about them in the conduct of their affairs. This description is couched in general terms and includes a minimum of technical terminology, but it builds on premises that need to be spelled out in more detail. For instance, the notion of 'discourse' has become widely used in the general academic literature, with such expressions as the 'discourse(s)' of science, of mathematics, or of psychiatry. These terms often replace established categorizations for disciplines or specialist activities as a way of focusing on what practitioners do rather than relying on established nominal labels.

'Formal linguists' are concerned with the grammatical rules of specific languages and dialects and look at discourse as a string of utterances that can be reduced to the grammar and lexicon of constituent sentences and analyzed by established analytical procedures. 'Sociolinguists,' on the other hand, deal with the talk of individuals speaking as members of specific groups and engaging in context-bound encounters where, along with grammar and lexicon, social and cultural forces constrain both what can be said and how it can be said. It follows that to participate in an encounter requires both linguistic and social knowledge.

But how does language interact with the social? Earlier sociolinguistic investigations turned to the published ethnographic literature for social information. In today's complex and rapidly changing societies, however, established social science concepts such as class, gender, and ethnic group cannot account for the ever-increasing diversity of the social ecologies in which we live. Social knowledge is increasingly seen as constructed through interaction. Discursive practice, the argument goes, rests on interaction, requiring the active participation of speakers and listeners, who use knowledge of the entire semiotic situation – of which speaking is a part – along with their linguistic knowledge to understand what is intended at any one point.

Theoretical Roots

A main motivation for interactional linguistic research is the search for replicable qualitative methods of sociolinguistic analysis that can provide insights into the inherent linguistic and cultural diversity that characterizes current communicative environments. These methods are also used to document the impact of the diverse environments on members' everyday lives without relying on traditional social science categorizations. It is by now evident that diversity can no longer be treated as primarily a matter of distinctions among bounded, locally homogeneous language/culture units. Regardless of where we live, diversity is all around us. A large and ever-growing number of empirical sociolinguistic studies testify to its extent and significance, even in areas and domains of activity traditionally considered to be monolingual and monocultural. Questions of diversity loom large in public debates and in the recent social science writings that have greatly transformed our current thinking about social and cultural phenomena. Yet so far most attempts to deal with the communicative import of diversity, particularly its role in everyday communication, continue to rely on essentialized, taken-for-granted notions of culture and group on the one hand and dialect, style, or speech variety on the other. Such attempts to explain what happens in talk in terms of extra-communicative notions, whose relationship to real-life discursive practices is highly questionable, are unlikely to yield replicable results.

The 1960s writings on 'ethnography of communication' (EC) in a sense laid the foundation for current IS research. In his well-known 1960s critique of post–World War II Whorfian studies, Hymes (1962) argued that the failure of current research to provide empirical validation of relations between linguistic and

cultural variability may be a result of the fact that, contrary to the prevailing assumptions, variability is not just a matter of distinctions among community-wide, presumably homogeneous grammatical and semantic structures. As Hymes (1974) suggests, many aspects of language function, which at the time had received little attention, play a major and often crucial role. His early programmatic writings set out an initial program for comparative research on both structure and function. The main argument was that such analyses, if they are to be empirically viable, must focus on specific situations of speaking, defined as interactively constituted, culturally framed encounters and not attempt to explain talk as directly reflecting the norms, beliefs, and values of communities seen as a disembodied, hypothetically uniform whole (Gumperz and Hymes, 1964, 1972). Instead of relying on community-wide generalizations as the bases for comparison, Roman Jakobson's (1960) notion of the 'speech event' was adopted as an intermediate level of analysis. Events, on the one hand, constitute units of verbal interaction, where what is said is socially and culturally constrained, so that valid ethnographic information on what are relevant norms and constraints can more readily and verifiably be obtained by event level analysis than if one were to build on generalizations about the community-wide values. At the same time, events are made up of stretches of talk that are subject to linguistic analysis in their own terms.

The initial EC studies concentrated largely on named, bounded gatherings rather than unmarked everyday talk – public performances, ceremonies, magical rites, ritual practices, political oratory, and judicial proceedings of various kinds – such as can be found in societies throughout the world. Ethnographic research served to gather information on beliefs, values, and appropriateness norms as they applied to the event. Findings tended to be generalized by formulating 'rules of speaking,' which governed participation and conduct in the event and choice among available speech styles that made up the communities' linguistic repertoires (Bauman and Sherzer, 1989; Blount and Sanches, 1977; Sanches and Blount, 1975). Event-focused comparative investigations served to call attention to the analytical importance of situated talk and to the need for new data on inter- and intrasocietal variability of linguistic structures and language usage. Yet as Brown and Levinson (1978) demonstrated, structuralist usage rules can never be made precise enough to predict what people actually do with talk. Among other things, they fail to account for the many, often unforeseeable contingencies that govern everyday behavior, as was argued in Bourdieu's (1977, 1991) well-known critique of structuralism.

When detailed descriptions of situated performances became available, the notion of 'event' as the extralinguistically defined unit of language usage also turned out to be untenable. Anthropologist-folklorists concentrating on verbal performance discovered that, more often than not, events were not clearly bounded. Rather, the participants' definition of what the relevant context is 'emerged' in the course of the performance itself (Bauman, 1988; Bauman and Briggs, 1990; Hymes, 1981). In such cases, as Hanks puts it in a well-known article on genre: "The idea of objectivist rules is replaced by schemas and strategies, leading one to view genre as a set of focal and prototypical elements, which actors use variously and which never become fixed in a unitary structure" (1987: 681, quoted in Bauman and Briggs, 1992). That is to say, invocations of context are perhaps best seen as communicative strategies for conveying indexical information, and we do not need to confine event analysis to named entities. Any string of utterances bounded by a detectable beginning and an ending that provide evidence for the outcome can be treated as an event.

Initial insights into the cognitive functioning of context invocation come from studies of 'code switching' (Auer, 1998), a term that is commonly used to refer to alternation among different languages or language varieties within the same community. Such alternations are found throughout the world, particularly in situations of rapid social change, and are frequently described via rules that specify the situational constraints governing language usage. In the old Roman Catholic Church service, for example, Latin was considered appropriate for prayer, while for sermons, the native language was to be employed. Yet if we examine switching as it enters into the discursive practices that constitute an event, it soon becomes apparent that the situation is more complex. As with the folk performances mentioned above, it is not the situation that determines language use; rather, it is the language or style, among other signs, which, when interpreted in relation to the ongoing talk, evokes a shift in contextual presuppositions. Code switching, in other words, functions as an metapragmatic signaling strategy that is employed indexically to suggest or evoke an 'envisionment' that yields the presuppositions in terms of which constituent messages are to be understood.

While both event evocations and code-switching function metapragmatically (Silverstein, 1976, 1993), they are 'phenomenologically distinct' (to use the current linguistic anthropologists' term). Event analysis yields general information or envisionments about

what is expected in the event as a whole and what the likely outcomes are. Code switching, on the other hand, is signaled via shifts at the level of individually isolable grammatical forms. Such shifts can be seen as indexical 'contextualization cues,' which, when processed simultaneously with grammatical and lexical signs and nonlexicalized background knowledge, serve to construct the contextual ground for turn by turn, situated, sentence-level interpretation and thereby suggest how constituent messages should be understood (Gumperz, 1982). In other words, contextualization cues represent speakers' ways of providing information to interlocutors and audiences about how language is being used at any one point in the ongoing stream of talk. What sets them apart from lexicalized metadiscursive signs is that they include purely suprasegmental signs, such as stress, intonation, volume, rhythm, and so forth. Since no utterance can be pronounced without suprasegmental signs, contextualization cues are ever present in the talk. They provide direct evidence for the necessary role that indexicality plays in talk.

Contextualization strategies signal by cueing indirect inferences. Since in conversation we could not possibly express all the information that interlocutors must have to plan their own contributions and attune their talk to that of their interlocutors, it is easy to see the reason for this indirectness. But finally and perhaps most importantly, indirect (not overtly lexicalized) signaling mechanisms are for the most part culturally or subculturally specific. For example, prosody, rhythm, and phonetically marked locally specific features of pronunciation are among the principal means by which we identify where people are from and 'who' they are – that is, assess their social identity. In fact, we are socialized into society via indexical communication, and through indexical signs we indicate our 'stance' *vis-à-vis* what is happening (Ochs, 1996).

If we accept that (a) interpretation is always context dependent, and (b) that contextual presuppositions shaping interpretations are themselves subject to constant change in the course of an interaction, then we cannot expect to find the kind of one-to-one mappings of form to meanings that we associate with referential communication. Contextualization cues serve to retrieve the frames that channel the interpretive process by trimming the decision-making tree – that is, limiting the range of possible understandings.

In talking about the functioning of indexical signs in interpretation, it becomes necessary to distinguish between meaning in the linguists' sense of reference and 'situated inferences.' The latter are crucial in communicative practice. In everyday talk, situated inferences always take the form of assessment of what a speaker intends to convey by means of a message, and these are often quite different from propositional content. For example, if Giovanni and Paolo had just been talking, and I asked the former, "What did you do with Paolo?" he will not answer, "I made a statement" or "I performed a speech act." A more likely answer would be, "I asked him for a favor" or "I asked him if he was free this evening." Moreover, even if Giovanni had said, "I asked him a question," I would not take this as referring to grammatical or speech act categories but as rather as telling me what he wanted from Paolo. Communicative practices are forms of actions, and conversational inferences are made by human agents acting in the real world.

By arguing that all communication is intentional and based on inferences, we are in some ways building on Garfinkel's notion of interpretative procedures to look at the inferential aspects of speaking. But Garfinkel is not specific as to what he means by inferencing or by the 'method' by which members' interpretive processes can be retrieved, apart from saying that we need to resort to background information on how and why a particular inference came about. How do we know what kinds of background knowledge are relevant at any one time? Is it enough simply to speak of 'extra-communicative background knowledge'? We must assume that information about contextual frames and how they interact with grammar and background knowledge is communicated in the course of discourse-level communication, where discoursing is treated as an intrinsically interactive process. It becomes necessary to clarify the specifics of what happens in the interaction as such, to assess what is intended.

Conversational analysts (Atkinson and Heritage, 1986) set out to implement Garfinkel's program. Their work has shown brilliantly what can be learned through detailed sequential analyses of speaking practices. Sequencing alone cannot by itself account for situated interpretation. Sequential ordering relies on just one of the many indexical processes that affect inferencing. Assessments of communicative intent, at any one point in an exchange, take the form of hypotheses that participants in an encounter can either confirm or reject in the course of an exchange. As conversational analysts point out, focus on members' procedures is a necessary analytical prime. The problem for IS then becomes not just to determine what is intended, but to also discover how interpretive assessments relate to the signaling processes through which they are negotiated.

How can we overcome the inherent ambiguity of inferential processes? In my own empirical field

studies, I have worked out a set of procedures along the following lines. Relying on data from previously collected targeted ethnographic observations, the IS analyst begins with turn by turn scanning of the recorded materials at two levels of analysis: (a) content, and (b) grammatical form, prosody, and rhythmic organization to isolate event units. The units should be marked off from others in the recorded data by at least some thematic coherence and by detectable beginnings and ends. Lectures, ceremonies of various kinds, interviews – that is to say named units of the type normally studied by ethnographers of communication – exemplify one type of event. But event sequences can also be extracted from everyday conversations and other casual encounters. For instance, narrative sequences may alternate or come interspersed with more formal discussion, argument, banter, and the like. In performing this segmentation we seek to discover natural interactive sequences to provide empirical evidence either to confirm or disconfirm analysts' interpretations – evidence against which to test assumptions about what is intended elsewhere in the sequence. These event sequences then form the base units for further analysis of conversational inferencing.

In phase two of the analysis, events are transcribed. The goal here is to prepare 'interactional texts' by setting down on paper all those perceptual cues – verbal and nonverbal, segmental and nonsegmental, prosodic, paralinguistic, and so on – shown by past and ongoing research to be demonstrably relied upon by speakers and listeners as part of the inferential process. This enables us not only to gain insights into situated understandings, but also isolate recurrent form–context relationships and show how they contribute to interpretation. These relationships can then be studied comparatively across events to yield more general hypotheses about members' contextualization practices.

In turning to conversational inference and its role in communicative practice, let me give some concrete examples to show how I view the process of understanding. Some time ago, while I was driving home from the office, my radio was tuned to a classical music station. At the end of the program the announcer, a replacement for the regular host who was returning the next day, signed off with the following words: "I've enjoyed being with **you** these last two weeks." I had not been listening very carefully, but the extra strong stress and volume on *you*, in a syntactic position where I would have expected an unaccented pronoun, caught my attention. It sounded as if the speaker was producing the second part of a formulaic exchange of compliments. But since there was no one else who could have spoken the first part (something like: "I enjoyed **being** with you") on the program, I inferred that by the way the host contextualized his talk, he was indirectly – without putting it "on record" – implicating (Grice, 1989) the first part, something like: "I hope you have enjoyed listening to me" (Gumperz, 1996). A second, somewhat more complex example comes from my analysis of the crossexamination transcript of the victim in a rape trial.

> Counsel: "You knew at the time that the defendant was interested in you, didn't you?"
> Victim: "He asked me how I'd been … just stuff like that."

In both cases, I had to search my memory of past communicative experience to construct a likely scenario or narrative plot that might suggest possible interpretations. In example one, my initial hypothesis conflicted with what I knew from listening to the radio program. My search triggered a different, more plausible scenario. In the second example, I relied on what I knew about crossexaminations as adversarial trial proceedings, where the attorney attempts to expose weaknesses in the defendant's testimony. But while these general facts tell us something about participants' motives in their choice of verbal strategy, we need to turn to what they actually said to understand what they intended to convey. By the words he chose, and by the way he contextualized his talk, the counsel raised the possibility that the defendant and the victim had a prior relationship. The victim's move, on the other hand, positioned as it is immediately after the attorney's question, implicates a different scenario, one where the two were merely casual acquaintances. In this way she sought to deny and in a sense ward off the questioner's potential attack on her testimony by suggesting another implicature.

I use the term 'activity' or 'envisionment' to refer to the above type of constructs. My claim is that all interpretation rests on such constructs. 'Activities' are an aspect of what Goffman (1974) calls 'frames' and are subject to constant change in the course of the exchange. That is, they do not apply to events as wholes; rather, they apply to each component move. I argue that, ultimately, all interpretation at the level of discursive practice relies on these constructs.

This view of understanding has some similarity to cognitive scientists' notions of 'scene,' but IS sees activities as evoking the actions of actors engaged in strategically formulating and positioning their moves to accomplish communicative ends in real-life encounters. In so doing, they rely on their presuppositions about mutual rights and obligations, as well as on ideologies of language and individuals' personalities, to get their message across. This implies that, in

addition to meaning assessment in the established sense, there are always social relationships that are continuously negotiated and renegotiated by means of the same interpretive processes by which content is assessed.

It is useful to distinguish between two levels of inference in analyses of interpretive processes: (a) global inferences of what an exchange is about and what mutual rights and obligations apply, what topics can be brought up, and what is wanted by way of a reply, as well as what can be put in words and what is to be left implied; and (b) local inferences concerning what is intended with any one move and what is required by way of a response. In this way it becomes possible to account for changes in frame as a function of the sequential positioning of moves. Both levels of interpretation involve activities as cognitive constructs. The first is related to what Goffman calls 'framing,' while the second deals with something like the conversational analyst's 'preference organization.' While contextualization cues assist in retrieving the knowledge on which activity constructs are based, they do not work in isolation. Interpretation always relies on cooccurring symbolic, lexical, and indexical signs. Signs such as prosodic contextualization cues, pausing, and others are usually produced and interpreted without conscious reflection and are therefore particularly useful in revealing frequently overlooked aspects of the interpretive process, which tend be highly sensitive to cultural variability.

Interactional sociolinguistics does not claim, of course, that the methods described here solve the problem of interpretive ambiguity. The aim is to find likely solutions that are plausible in that they show how component actions cohere in the light of an event as a whole, whether it is a three-part string of moves or a longer encounter. Inferential procedures are not like assessments of the truth or falsity of specific interpretations. The method resembles conversational analysts' ways of reconstructing the general procedures that conversationalists employ in formulating specific actions. However, it goes beyond conversational analysis in that the concern is with situated online interpretation. In studies of intercultural and interethnic communication, these methods have been useful in detecting systematic differences in interpretive practices affecting individuals' ability to create and maintain conversational involvement.

Ultimately, agreement on specific interpretations presupposes the ability to negotiate repairs and renegotiate misunderstandings, agree on how parts of an argument cohere, and follow thematic shifts and shifts in presuppositions – i.e., sharing indexical conventions. A basic issue is to show how these tasks are accomplished, and it is for this reason that IS puts so much stress on contextualization processes. Such metapragmatic activity is important for participation in everyday interaction. Without metapragmatic strategies, conversationalists do not learn and do not profit from their own misunderstandings. And this clearly has to do with verbal ability at the level of communicative practice, because it is on such practices that our ability to assess and evaluate the significance of what we perceive rests.

Let me present one more example to illustrate the multiplicity of inputs to the interpretative process. A young elementary school student, when asked to read, replied, "Ah ca-an't read." The teaching assistant thought he meant to say that he was not able to read. Examples like this have often been cited in the literature on classroom learning in support of assertions that African–American students have difficulty with literacy learning. But when we discussed this example with a group of African–American graduates, they pointed out that the expression carried contoured intonation, and given the expression's positioning after the teaching aid's question they would interpret the student as saying, essentially, "I don't want to do it right now. I want company in reading." On the basis of experiences like these I became alerted to the fact that for those familiar with African–American conventions, the differences between 'contoured' and 'noncontoured' intonation may carry information.

Such uses of prosody are not only found in African-American speech. Consider the following example I recently heard in Cambridge from someone talking about his college, King's. "Fellows of King's are well known, to fellows of King's." The second phrase is set off from the first, and therefore foregrounded, by lowering of pitch and volume. This suggests that *well known* is restricted, so as to highlight the interpretation, and that the compliment phrase applies only to other fellows of King's, not to the public at large. Understanding, as structuralists have taught us always relies on selective perceptions based on our knowledge of oppositions, and this is true for indexicals as well as for symbolic relationships. All interpretive assessments are relational. They are made with reference to something else, not necessarily directly represented in talk. Nevertheless, as the examples show, assessment involves reasoning that is intrinsically dialogic, in the sense that positioning within an exchange is essential to communication.

Conclusion

Interactional sociolinguistics does not claim to present an integrated grand theory of language, culture, linguistic ideology, interaction, and communication.

In view of the many radical transformations that mark much of the known world, such a theory would be premature. Rather, it draws upon an eclectic array of recent theories to find ways of uncovering the phenomenological grounding of communicative problems in today's social life to sharpen our understanding of the multiplicity of forces that underlie interpretation and thereby draw on what we have learned in recent years to prepare the ground for more productive theorizing.

Interactionism

W Housley, Cardiff University, Wales, UK

© 2006 Elsevier Ltd. All rights reserved.

The term 'interactionism' refers to a sociological approach that can be summarized in terms of the following positions. First, that interactionism is a broad perspective in sociology that owes its origins to work carried out by sociologists working at the University of Chicago between the World Wars I and II during the last century. This description applies particularly to the work of Robert Park and W. I. Thomas. However, interactionism is also connected with the tradition of symbolic interaction developed through the social psychology of George Herbert Mead, who was also based at the University of Chicago, in his famous book *Mind, self and society* (1934). Mead's triadic formulation expresses a core theme of interactionism, namely the continuum between individuated forms of life and 'wider' social processes. Other influences include the Iowa School associated with the more positivistic work of Manford Kuhn, and the later work and distinct interactionist ideas associated with Erving Goffman. The precise origins of interactionism and symbolic interactionism are contested territory (Fisher and Strauss, 1978).

Interactionism is often associated with qualitative forms of inquiry and ethnography. However, in terms of precedents and origins, the Chicago School did not favor the qualitative over the quantitative and utilized a range of methods during the course of research into urban life. However, it is the case that sociologists associated with interactionism have developed and promoted qualitative and ethnographic forms of inquiry that resonate with interactionist concerns (Gubrium and Holstein, 2002; Atkinson and Housley, 2003). Issues and innovations surrounding methodology have been an important conduit for the export and reception of interactionist ideas across the social sciences.

Interactionism is committed to empirical work and seeks to explore the social and moral organization of the world. More specifically, interactionist studies have explored the role of labeling and social types in institutions and organizations. For example, the processing of people through medical institutions is tied to interactional work associated with moral ascription, accounts, and definitions that have a powerful effect on medical outcomes and the access to scarce medical resources. W. I. Thomas's dictum concerning the 'definition of the situation' (Thomas, 1923) is seen as crucial in understanding the workings of such forms of social organization. The concept of career (Goffman, 1963; Matza, 1964) has been central to examining the formation and transformation of self and identity through time and has been important in conceptualizing social identity as an active process rather than an ascribed state where action and agency have little relevance. This notion has contributed to the development of interactionist theories of deviance (Matza, 1969), educational experience (Hargreaves *et al.*, 1975) and emotional labor (Hochschild, 1983). A crucial idea here is the way in which this perspective relates to the 'interaction order,' where such an order is accomplished through interaction on a routine and mundane basis. Knowledge and expertise, for interactionists, is grounded in situated practices and action. Thus, medical or educational knowledge is realized in action and not in second hand accounts or decontextualized 'bodies of knowledge'. Consequently, interactionist studies have contributed extensively to the sociology of the professions, knowledge, and expertise (Atkinson, 1981).

For interactionism, society is a continuum within which notions of the 'macro' and 'micro' have little relevance. Social organization is viewed as an emergent property of interaction and agency. Consequently, the way in which interactionism tackles notions of organization has relevance and resonance with more recent debates on complexity and organization.

Interactionist inquiry has sought to explore the character and organization of social phenomena through the exploration of face-to-face interaction, language, gesture, dress, narrative, stories, practices, and other 'documents of life' (Plummer, 1983). The spatial scales of interactionism do not merely involve 'people' and 'interaction.' Rather space and place have important roles in early and contemporary interactionist forms of inquiry. These conceptual concerns can be found in the Chicago School's examination of subculture and the social ecology of the city to studies of community life and institutional interaction. Furthermore, the cultural and linguistic turns within the social sciences were not felt particularly strongly within this tradition due to the fact that both linguistic and cultural practices have always been central to interactionist concerns. As Rock (1979: 116) notes, forms of language mediate the "workings of consciousness, the self and social interchange." Consequently, for interactionism, language is a central feature of social life and forms the bedrock from which society is understood to emerge and unfold within scenes, settings, and encounters. Language and symbolic action are seen as central to the

practical accomplishment of the morality of types, moral careers, being, and becoming. Furthermore, the work of Erving Goffman (1959) on face-to-face interaction was influential in the development of conversation analysis and Harvey Sacks' ethnomethodological work on the interactional organization of talk. The wider movement of discourse studies exhibits a conceptual debt to Goffmanian metaphor and thinking. In more general terms, interactionism demonstrates how culture is used and accomplished within situated action and has, in many respects, pre-empted many of the observations touted by 'postmodernism' in relation to social identity and linguistic practice (Atkinson and Housley, 2003: 159–167). The focus of interactionism on the social as process has become an accepted principle within the social sciences, although this accomplishment has often been at the expense of acknowledging the important role of interactionism in promoting this understanding.

Interactionism has cross disciplinary relevance within the social sciences and is of import to linguistics due to its long association with the examination of the role of language and language use in social context. The pragmatic basis of interactionism is consistent with its North American origins, although its reception and use in the social sciences is universal. Interactionism continues to influence sociology, cultural studies, studies of language and discourse, and social science methodology. In many respects, social science has now taken on board interactionist insights as part of core orthodoxy.

Interactive Fiction

N Montfort, University of Pennsylvania, Philadelphia, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

The term '*interactive fiction*' (IF) refers to computer programs that provide textual, natural language output and accept a similar sort of input from the user, who is also called the '*player*' or '*interactor.*' The input from the interactor influences events in a simulated world, while the output describes what happens in this world. An IF program, often called a '*game*' or sometimes a '*work of IF*,' may involve graphics and sound, but a natural language exchange and a simulated world are, traditionally, the defining elements. Interactive fiction works are computer programs, simulated spaces, and generated narratives, and while they fall into the broad category of computer games, they have literary aspects as well. The complex nature of IF helps to explain how these simple-looking programs have continued to interest authors, interactors, and critics for several decades.

Early IF works such as *Adventure* and *Zork* were originally programmed and enjoyed noncommercially, beginning in the mid-1970s. In the 1980s, after home computers appeared, IF became big

business. Thanks to the existence of sophisticated, free development systems for IF, individual authors have continued to make many interesting literary and gaming innovations.

Formal Qualities of Interactive Fiction

The parser and the world model are the essential components of an interactive fiction work. The parser is responsible for translating the text typed by the interactor into meaningful actions within the simulated world. The world model drives that simulation. It models the setting or space, the objects within the space, the physical laws, and even other characters.

The interactor's input usually consists of short commands to a character, called the 'player character.' Thus, typing *ask the librarian about the freeway* commands the player character to question another character, *pick up the book* means the player character is to take possession of a book that is in the immediate area, and *go east* is a command to walk in the direction specified. Frequent commands can usually be abbreviated; for instance, *east* means the same thing as *go east,* and can be further abbreviated to *e*. It is also possible to type directives that affect the game state rather than indicating action within the simulated world; *quit, save,* and *restart* are examples of these. For examples of interaction, see Figure 1.

Interactive fiction works are often able to recognize most meaningful inputs, since the textual exchange that goes on is supposed to refer to the simulated world. Simple actions within the world, and some forms of conversation with characters, are usually possible. Interactive fiction parsers can be brittle, however; unanticipated phrasings of an ordinary command, and less usual sorts of input, are sometimes not understood. Rule-based techniques have been used for understanding input, a task that involves some complexities, such as resolving the referents of pronouns used by the interactor.

The IF world is simulated with a graph of locations or areas, also called 'rooms' in deference to the first IF work, *Adventure*. (That work of IF was set in a cave, areas of which were called 'rooms' by cavers.) These locations may be connected in arbitrary ways, creating mazes or impossible configurations. They may contain not only the player character but also other characters, containers, objects, and vehicles. The player character is also a container of sorts, carrying objects that can be enumerated by typing *inventory*. In many early adventure games of this cave-crawl sort, the aim was to explore a simulated space, finding treasures and keys along the way. Players often mapped the environment on paper. Interactive fiction soon required other sorts of activities, such as the interrogation of suspects, the understanding of principles behind an unusual world, and the expression of one's understanding through actions in the world.

History and development

Adventure was the first work of IF and may still be the most famous. It was initially written in Fortran by Will Crowther, probably in 1975, on a PDP–10 owned by Bolt, Beranek, and Newman, the same computer that sent the first e-mail message. Crowther's program accepted one- or two-word commands, simulating a specific cave in Kentucky that he had explored. The interactive framework and the presence of puzzles was inspired by the noncomputer role-playing game *Dungeons and dragons*. Don Woods, at Stanford University, found the program online; he polished and expanded it, releasing the version that became canonical in April 1976. It spread through the ARPANET in the late 1970s. A common joke was that *Adventure* had set the whole field of computing back by two weeks as everyone who had access to a computer struggled to solve it. *Adventure* was never an official project for either of its creators, who allowed it to be freely distributed and reimplemented.

Several *Adventure* players wrote their own games and tried to improve on this instant classic. Tim Anderson, Marc Blank, Bruce Daniels, and Dave Lebling wrote a less realistic but more elaborate cave crawl, *Zork,* at the Massachusetts Institute of Technology, in MDL on a PDP–10. *Zork* (also known, briefly, as *Dungeon*) accepted longer input phrases, extended the world model to include containers and vehicles, and featured a character, the thief, who was elaborately described and who played an interesting role in the interactive experience. Other early IF included the massive *Acheton* (by Jon Thackray, David Seal, and Jonathan Partington) and other games for Cambridge University's Phoenix mainframe computer, as well as *Haunt,* created by John Laird at Carnegie Mellon University.

By 1978 Scott Adams had started selling his *Adventureland,* a primitive, *Adventure*-like game for home computers that was the first of a popular series of games sold by U.S.-based Adventure International. Scott and Alexis Adams also published the code to their *Pirate adventure* in a magazine in 1980, offering an important early illustration of how IF could be programmed.

Three of the *Zork* creators joined with others to found Infocom in 1979. Infocom became the most successful U.S. IF company, developing 35 titles, many of which were both engaging as games and

Attic
The attics, full of low beams and awkward angles, begin here in a relatively tidy area
which extends north, south and east. The wooden floorboards seem fairly sound, just as
well considering how heavy all these teachests are. But the old wiring went years ago, and
there's no electric light.

A hinged trapdoor in the floor stands open, and light streams in from below.

>go north

Old Winery
This small cavity at the north end of the attic once housed all manner of home-made wine
paraphernalia, now lost and unlamented. Steps, provided with a good strong banister rail,
lead down and to the west, and the banister rail continues along a passage east.

You can see a labelled glass demijohn (which is closed) (in which are a nasty-looking red
battery and a tourist map) here.

As you disturb the still air, the attic key, which was balanced on top of the demijohn,
slips onto the floor and disappears into a crack in the floorboards. Your spirits sink as
it does, rattling down some distance. How on earth are you going to get it back?

>look at the map
The good news is that it has excellent grid references, which are easy to look up. The bad
news is that it is a map of central Hamburg.

>open the demijohn
Your hands slip on the screw-top of the demijohn and can't get a grip.

>
```

Figure 1 The beginning of an interaction with *Curses,* an important interactive fiction work from the mid-1990s, is shown in this screenshot. The interactor typed the text that appears after the > prompt; the rest of the text was printed by the computer program.

compelling from a literary standpoint. These included *Zork I-III,* a home computer trilogy adapted from the mainframe *Zork*; *Deadline,* a mystery by Blank; *A Mind Forever Voyaging,* a dystopia by Steve Meretzky; *Trinity,* a politically charged fantasy by Brian Moriarty; and an IF adaptation of *The hitchhiker's guide to the galaxy,* which Douglas Adams wrote with Meretzky. While Infocom dominated IF in the United States, other companies developed interesting and innovative works: Synapse recruited Robert Pinsky to write *Mindwheel,* which was published in 1984; Thomas Disch, a well-respected novelist, created *Amnesia* (published in 1986) with the Cognetics Corporation.

During the 1980s, Australia's Melbourne House released several games, including an adaptation of J. R. R. Tolkien's *The hobbit* by Philip Mitchell and Veronika Megler. This 1983 release was still based on textual commands and replies, but it also incorporated graphics that showed what the current area looked like, a technique first used in *Mystery house,* a 1980 game by Ken and Roberta Williams. In the United Kingdom, Level 9 was the first major IF company. Founded by Pete, Mike, and Nick Austin, the company's many IF releases include the 1983 *Snowball,* a science-fiction adventure by the three brothers, and Pete Austin's 1987 *The knight orc,* in which the player character is humorously hateful. Magnetic Scrolls, founded in the United Kingdom in 1984 by Anita Sinclair, Ken Gordon, and Hugh Steers, started off producing IF for more advanced 16-bit computers. Their first title was *The pawn,* written by Rob Steggles, with graphics by Geoff Quilley.

The commercial success of IF did not last long into the 1990s. While this has led some to believe that the form is dead or irrelevant, IF actually seems to have simply returned to the production and distribution model of the late 1970s: Today, people skilled as both programmers and writers develop IF unofficially and offer their work for free online, just as Crowther and Woods did. Development has been enabled by free IF languages, mainly Graham Nelson's Inform and Mike Roberts's Text Adventure Development System, and has been spurred on by the online IF Competition, a contest for short games that has run annually since 1995.

Since developments in the mid-1990s (most notably, Graham Nelson's 1993–1995 *Curses* (**Figure 1**), released at the same time as Inform), IF authors have continued to innovate. Dan Shiovitz's *Bad machine* (1998) joins concepts of 'codework' (in which English and programming language typography are combined) with IF's systematic simulated world. Adam Cadre's *Varicella* (1999) is an intricate palace intrigue with a cast of vile characters. Emily Short's *Galatea* (2000) situates a complex 'chatterbot' (or conversational character) in a museum gallery. Andrew Plotkin's *Shade* (2001) presents what looks like a clichéd one-room game in an apartment, but the player character's ordinary actions reveal a disturbing reality.

While this summary history has only covered English-language IF, IF has been written in other languages at least since the commercial era of the 1980s. Communities of independent IF authors who write in German, Italian, Spanish, and other languages have been active since the 1990s.

Connections to other Literature and Computing

The many aspects of IF suggest connections to literary, computational, and gaming developments in the past, as well as to broader categories of game and literature. Because IF has several interesting aspects, it is sometimes marginalized in discussions of computer games or of electronic literature by those would prefer to place it in someone else's category. Interactive fiction is also less approachable and more demanding than many other types of computer literature or games. However, some find IF particularly interesting precisely because of the demands it places on the interactor and because of its many unusual aspects.

From one perspective, IF works are machines for producing texts. The history of such machines extends back beyond the electronic computer to the ancient Chinese oracle, the I ching, and to Raymond Llull's 13th-century wheel for generating all possible true propositions about God. In the 20th century, such machines took more explicitly literary forms; Raymond Queneau's *Cent mille millard de poèmes* (1961), a stack of sonnets 10 layers deep whose 14 lines can each be interchanged, is one example. Although the *Poèmes* are quite unlike *Adventure* in their tone, appearance, and workings, the author of an IF does have to deal with the fact that a particular text may be seen in many different contexts, just as Queneau did. Formality regularly is sometimes part of the answer to this difficulty, as it was in the *Poèmes*.

An IF program is also a machine for understanding texts. It shares this quality with Terry Winograd's 1972 system SHRDLU, a powerful system for natural language understanding that had a world model and parser and that seems to have been an indirect influence on early IF. SHRDLU graphically presented a 'blocks world' that could be manipulated by a robot, who was commanded with sentences, but it was not designed to offer a compelling space for exploration, a challenging quest, or an overarching riddle. Another predecessor was Joseph Weizenbaum's 1964–1966 *Eliza*, which ran the *Doctor* script to simulate a psychotherapist. *Eliza/doctor* did not understand inputs deeply and did not model a world, but it did provide a compelling scenario that drew people to interact with it.

Interactive fiction grew out of a tradition of recreational computing, one that extended back past the 1962 creation of *Spacewar,* the first modern video game. Numerous simple but engaging games had been developed before *Adventure;* one important one was the much less descriptive, but nevertheless

innovative, cave game *Hunt the wumpus,* written by Gregory Yob in Basic in 1972. *Adventure,* in addition to being the first IF work, was also the first in the adventure game category. Interactive fiction has generally been an influential part of that category, which takes its name from *Adventure* and includes point-and-click graphical adventures that do not involve an exchange of language, such as *Myst*. Although less directly descended from interactive fiction, action-adventure games such as *Tomb raider* have also been influenced by IF.

While IF makes up an important part of computer gaming, the exchange of writing that takes place allows IF to have interesting literary dimensions as well. IF works, which have been presented at literary readings and have been taught and studied in literary contexts, are examples of electronic literature, as are works of hypertext fiction, chatterbots (in the vein of *Eliza/doctor*), interactive poems, and other electronic documents and computer programs that have important literary aspects.

Intercultural Pragmatics

In her book *The Opposite of Fate* the American writer of Chinese descent, Amy Tan (2003: 54), writes of a time when tragedy hit her life and when, as a result, she decided to quit the doctoral program in linguistics that she was pursuing at the time: "The doctorate, I decided, would be a worthless appendage. Besides (...), how was I bettering the world by teaching others to examine the intricacies of dead languages and the like?" Amy Tan's words echo these of the linguist Dell Hymes (1996: xii), who speaks of the fascination of modern linguistics with "aspects of language as an abstract formal device" and who sees as a more worthwhile and more timely goal "to think about language as part of life" (Hymes, 1996: x) and to develop a "linguistics that someone needs (...) – a linguistics that every student of human life should know, that one would like everyone to know (...), that should be part of general education" (Hymes, 1996: 220).

Intercultural pragmatics is a part of contemporary linguistics which is most concerned with "language as a part of life," indeed, with language as it affects millions of lives in the contemporary world, and which arguably every student of human life should know. It is a discipline that has developed in response to what Istvan Kecskes (2004), the editor of the new journal *Intercultural Pragmatics*, calls "the challenges of a new era."

These challenges of a new era involve, above all, interaction among people from different cultures. Pragmatics as a part of linguistics has always been concerned with interpersonal interaction – but (as will be discussed below) in the past it was often locked in a monolingual and monocultural framework, derived,

innovative, cave game *Hunt the wumpus,* written by Gregory Yob in Basic in 1972. *Adventure,* in addition to being the first IF work, was also the first in the adventure game category. Interactive fiction has generally been an influential part of that category, which takes its name from *Adventure* and includes point-and-click graphical adventures that do not involve an exchange of language, such as *Myst*. Although less directly descended from interactive fiction, action-adventure games such as *Tomb raider* have also been influenced by IF.

While IF makes up an important part of computer gaming, the exchange of writing that takes place allows IF to have interesting literary dimensions as well. IF works, which have been presented at literary readings and have been taught and studied in literary contexts, are examples of electronic literature, as are works of hypertext fiction, chatterbots (in the vein of *Eliza/doctor*), interactive poems, and other electronic documents and computer programs that have important literary aspects.

Intercultural Pragmatics

In her book *The Opposite of Fate* the American writer of Chinese descent, Amy Tan (2003: 54), writes of a time when tragedy hit her life and when, as a result, she decided to quit the doctoral program in linguistics that she was pursuing at the time: "The doctorate, I decided, would be a worthless appendage. Besides (...), how was I bettering the world by teaching others to examine the intricacies of dead languages and the like?" Amy Tan's words echo these of the linguist Dell Hymes (1996: xii), who speaks of the fascination of modern linguistics with "aspects of language as an abstract formal device" and who sees as a more worthwhile and more timely goal "to think about language as part of life" (Hymes, 1996: x) and to develop a "linguistics that someone needs (...) – a linguistics that every student of human life should know, that one would like everyone to know (...), that should be part of general education" (Hymes, 1996: 220).

Intercultural pragmatics is a part of contemporary linguistics which is most concerned with "language as a part of life," indeed, with language as it affects millions of lives in the contemporary world, and which arguably every student of human life should know. It is a discipline that has developed in response to what Istvan Kecskes (2004), the editor of the new journal *Intercultural Pragmatics*, calls "the challenges of a new era."

These challenges of a new era involve, above all, interaction among people from different cultures. Pragmatics as a part of linguistics has always been concerned with interpersonal interaction – but (as will be discussed below) in the past it was often locked in a monolingual and monocultural framework, derived,

essentially, from the English language and Anglo culture. In the contemporary world, however, a monolingual and monocultural perspective on language use is no longer tenable, and in fact has become glaringly irrelevant and obsolete.

In a recent book entitled *Becoming Intercultural*, the Korean-American scholar Young Yun Kim (2001: 1) writes: "Millions of people change homes each year, crossing cultural boundaries. Immigrants and refugees resettle in search of new lives (...) In this increasingly integrated world, cross-cultural adaptation is a central and defining theme." Cross-cultural adaptation is particularly relevant to immigrants and refugees, but the need for cross-cultural understanding extends further. In modern multiethnic societies, newcomers need to learn to communicate with those already there; and those already there need, for their part, to learn to communicate with the newcomers. In a world that has become a global village, even those living in their traditional homelands need to develop some cross-cultural understanding in order to be able to cope with the large world confronting them in a variety of ways.

Language has been defined, traditionally, as a tool for communication, and linguistics as the study of language. In practice, however, the dominant linguistic paradigm of the second half of the 20th century had very little to do with human communication, and even less with problems of cross-cultural communication. In the last three decades, however, linguistics has 'greened' and the formalistic approaches of generative grammar have been supplemented, if not supplanted, by approaches more concerned with meaning, culture and people, than with formalisms.

The "pragmatic turn" (Mey, 2004) in linguistics is part of this 'greening.' But the paradigms of pragmatic research that at first came to the fore were derived largely from philosophical speculation based on English (especially in the works of Austin, Searle, and Grice) and did not reflect the mass phenomenon of interaction among people from different cultural backgrounds. As Kecskes writes in his editorial in the first issue of *Intercultural Pragmatics*, "We live in an age of globalization that is characterized by rapid changes in every field of life. This is resulting in a revision of theories and ideas in several branches of the humanities and sciences, including pragmatics. The existing paradigms cannot always accommodate new research. This is especially true for pragmatics, which is considered a perspective in language and communication rather than the study of a particular aspect of language" (Kecskes, 2004: 1).

Intercultural pragmatics studies, above all, problems arising in communication between people with different cultural backgrounds and different cultural expectations. A good example of such problems is provided by Amy Tan's account of the difficulties that her Chinese-American mother continually faced in her interactions with other Americans. As Amy Tan reports, "... some of my friends tell me they understand 50 percent of what my mother says. Some say they understand 80 to 90 percent. Some say they understand none of it, as if she were speaking pure Chinese. But to me, my mother's English is perfectly clear, perfectly natural. It's my mother tongue. Her language, as I hear it, is vivid, direct, full of observation and imagery. That was the language that helped shape the way I saw things, expressed things, made sense of the world." Amy Tan's mother's English was fluent, but its grammar was non-standard, and her way of speaking made it appear "fractured", "broken", "limited" – and her "limited" communicative competence made her also appear to be limited as a person. "I know this for a fact, because when I was growing up, my mother's 'limited' English limited my perception of her. I was ashamed of her English. I believed that her English reflected the quality of what she had to say. That is, because she expressed them imperfectly her thoughts were imperfect. And I had plenty of empirical evidence to support me: the fact that people in department stores, at banks, and at restaurants did not take her seriously, did not give her good service, pretended not to understand her, or even acted as if they did not hear her."

Aware of the limitations of her communicative competence in English, Amy Tan's mother often got her daughter to speak to people on the phone pretending that she was her mother. For example, when Amy was fifteen, she had to call her mother's stockbroker in New York presenting herself as "Mrs. Tan."

> And my mother was standing in the back whispering loudly, 'Why he don't send me check, already two weeks late. So mad he lie to me, losing me money.' And then I said in perfect English, 'Yes, I'm getting rather concerned. You had agreed to send the check two weeks ago, but it hasn't arrived.' Then she began to talk more loudly. 'What he want, I come to New York tell him front of his boss, you cheating me?' And I was trying to calm her down, make her be quiet, while telling the stockbroker, 'I can't tolerate any more excuses. If I don't receive the check immediately, I am going to have to speak to your manager when I'm in New York next week.' And sure enough, the following week there we were in front of this astonished stockbroker, and I was sitting there red-faced and quiet, and my mother, the real Mrs. Tan, was shouting at his boss in her impeccable broken English.

What is at issue here is not just the grammatical incorrectness of the mother's English, but above all, her way of speaking – her loudness, her shouting, her

emotional intensity, her "directness" (as Tan describes it), her inability to use understatement such as "I'm getting rather concerned."

Amy Tan's attitude to, and interpretation of, her mother's difficulties is in itself instructive, as it reflects aspects of the confusion and theoretical insecurity that have until recently plagued the field of intercultural pragmatics, and to some extent still do. On the one hand, the vignettes offered in Amy Tan's book clearly show differences between Chinese communicative norms and expectations and the Anglo-American ones, and throw light on cultural misunderstandings related to those differences. On the other hand, Tan, like many linguists of her generation, is clearly frightened of stereotyping, and she prefers to deny the reality, or at least describability, of cultural differences such as those between Chinese and American culture, professing instead her faith in human universals. And yet her own experience, conveyed with great talent in her books, clearly reflects the reality of those differences, and the urgent need for them to be described and widely understood – especially in countries where people of different cultural backgrounds have to live together. Thus, at times Tan's observations and intuitions as a writer come into conflict with the ideologies that can perhaps be traced to her linguistic education in the 1970s.

In the 1970s, the pragmatic scene was largely dominated by the search for the universals of politeness and for the universal maxims of conversation. The widely accepted paradigms were those of Brown and Levinson's (1978) theory of politeness, which affirmed "pan-cultural interpretability of politeness phenomena" (Brown and Levinson, 1978: 288), and Grice's theory of conversation, which posited a number of universal conversational principles.

In 1978, Brown and Levinson set out "to describe and account for what is in the light of current theory a most remarkable phenomenon. This is the extraordinary parallelism in the linguistic minutiae of the utterances with which people choose to express themselves in quite unrelated languages and cultures" (Brown and Levinson, 1978: 60). A quarter of a century later, it is increasingly widely accepted that this "extraordinary parallelism" was largely an illusion due to that "light of current theory." What is seen as more remarkable today is the extent of cross-linguistic and cross-cultural differences in ways of speaking. Brown and Levinson (1978: 61) described it as their goal "to rebut the once-fashionable doctrine of cultural relativity in the field of interaction" and "to show that superficial diversities can emerge from underlying universal principles and are satisfactorily accounted for only in relation to them." Their major conclusion was that "interactional systematics are based largely on universal principles" (Brown and Levinson, 1978: 288). Today, it is increasingly accepted that those diversities in ways of speaking and interacting are not superficial at all and that they can be largely accounted for in terms of different cultural attitudes and values; and the "cultural relativity in the field of interaction" is increasingly seen as a reality and an important subject for investigation.

In 1983 this author presented, at a meeting of the Sydney Linguistic Circle, a paper entitled 'Different cultures, different languages, different speech acts: English vs. Polish' (Wierzbicka, 1985), which argued that the supposedly universal maxims and principles of politeness were in fact rooted in Anglo culture and which in time became the nucleus of her book *Cross-cultural Pragmatics* (Wierzbicka, 1991/2003). The paper argued, in particular, that the "freedom from imposition," which Brown and Levinson (1978: 66) saw as one of the most important guiding principles of human interaction, was in fact an Anglo cultural value, and that the avoidance of "flat imperative sentences," which Searle among many others attributed to the "ordinary conversational requirements of politeness," did not reflect "universal principles of politeness" but rather, expressed special concerns of modern Anglo culture. At the same time, some other linguists, too, were raising their voices against the 'universals of politeness' approach to pragmatics and were arguing in defense of culture as a key factor determining ways of speaking, trying to link the language-specific ways of speaking with different cultural values. The scholars who in the inhospitable post-Gricean climate of the 1980s (or so) were opposing a facile universalism and pioneering intercultural (as against pancultural) pragmatics, included, among others, Ho-min Sohn, the author of "Intercultural communication and cognitive values" (1983); Tamar Katriel, the author of *Talking straight: Dugri speech in Israeli Sabra culture* (1986); Yoshiko Matsumoto, the author of 'Reexamination of the universality of face: politeness phenomena in Japanese' (1988); James Matisoff, the author of *Blessings, curses, hopes, and fears: psycho-ostensive expressions in Yiddish* (1979); Thomas Kochman, the author of *Black and white styles in conflict* (1981); and Sachiko Ide, the author of a study on the Japanese value of *wakimae* or 'discernment' (1989). In the 1990s, the broadly-based intercultural pragmatics grew further, bearing rich fruit in the works of authors such as Donal Carbaugh, the author of *Talking American* (1988); Cliff Goddard, the author of papers such as 'Cultural values and 'cultural scripts' of Malay' and 'Communicative style and cultural values – Cultural scripts of Malay' (1997, 2000); Jean Harkins, the author of *Bridging two worlds: Aboriginal English*

and cross-cultural understanding (1994); Felix Ameka, the author of studies on Ghanaian conversational routines and the editor of a special issue of the *Journal of Pragmatics* on interjections (1992); Michael Clyne, the author of *Intercultural communication at work: Cultural values in discourse* (1994), and many others. Last but not least, an important role was played by two open-minded and cross-culturally alive journals: Jacob Mey's *Journal of Pragmatics* and Marcelo Dascal's *Pragmatics and Cognition*.

Outside linguistics, there were anthropologists who did not give in to the superficial and anti-cultural universalism of the time and who continued to focus on the language particulars and to probe the links between ways of speaking, ways of thinking, ways of feeling and ways of living. To mention just a few names and works, particularly important from a linguistic point of view: Catherine Lutz, the author of the classic book *Unnatural emotions: Everyday sentiments on a Micronesian atoll and their challenge to Western theory* (1988); Richard Shweder, the founder of cultural psychology and the author of *Thinking through cultures – Expeditions in cultural psychology* (1991); Dorothy Holland and Naomi Quinn, the editors of *Cultural models in language and thought* (1987); Roy D'Andrade and Claudia Strauss, the authors of *Human motives and cultural models* (1992), and Claudia Strauss and Naomi Quinn (1997), the authors of *A cognitive theory of cultural meaning*. Here, too, two journals played an important role: *Ethos* and *Culture and Psychology*.

There were also some philosophers who started to question the universalist pragmatic theories of Grice, Griceans, and neo-Griceans from a philosophical as well as cross-linguistic point of view. In particular, Wayne Davis (1998) argued in a book-length critique that "the Gricean theory has been barren" and that "the illusion of understanding provided by the Gricean theory has only served to stifle inquiry" (Davis, 1998: 3). "The Gricean explanation of common implicatures" is, Davis argued, "undermined by the existence of nonuniversal implicature conventions" (Davis, 1998: 183). For example, Grice and his followers had claimed that the correct interpretation of a tautology like *War is war* could be calculated from some universal maxims of conversation. Davis pointed out that this claim is refuted by the observation that such tautologies receive different interpretations in different cultures, and he concluded: "The moral is clear. Generalized tautology implicatures (...) are not explained by Gricean Maxims" (Davis, 1998: 46). In a similar context, Davis (1998: 168) quoted and endorsed the present author's own observation that "from the outset, studies in speech acts have suffered from an astonishing ethnocentrism" (Wierzbicka, 1985: 145).

> Many of the criticisms I present have been known for some time. But the import and seriousness of the defects individually and collectively have not been widely appreciated, and the problems have had little impact on the general acceptance of Gricean theory. The best known critics of the Gricean theory have either expressed confidence that solutions would be found within the Gricean framework (...) or presented alternative theories with similar defects (Sperber and Wilson, 1986). (...) Only one author (Wierzbicka, 1987) has argued that the conception is fundamentally flawed. (Davis, 1998: 3)

From the historical, as well as theoretical, point of view, it is important to note that a powerful impulse for the rise of intercultural pragmatics in the last decade came from the growing field of studies focussed on cross-cultural (or intercultural) communication. When in her 1986 book *That's not what I meant!* Deborah Tannen stated that "the future of the earth depends on cross-cultural communication," she was expressing a perception which was growing, especially outside academic circles, but also increasingly within. At a time when every year millions of people crossed the borders, not only between countries but also between languages, and when more and more people of many different cultural backgrounds had to live together in modern multiethnic and multicultural societies, it was becoming increasingly evident to many scholars that research into differences between cultural norms associated with different languages was essential for peaceful co-existence, mutual tolerance, necessary understanding in the workplace and in other walks of life in the increasingly global and yet in many places increasingly diversified world. It was more and more frequently noted that the once popular assumption that the principles of politeness were essentially the same everywhere and could be described in terms of universal maxims such as those listed in Leech's *Principles of Pragmatics* (1983) flew in the face of reality as experienced by millions of ordinary people – refugees, immigrants, the children of immigrants, caught between their parents and the society at large, cross-cultural families and their children, and also by monolingual stay-at-homes who suddenly found themselves living in societies that were ethnically, culturally and linguistically diverse.

The tremendous practical importance of identifying, and describing, the culture-specific norms of politeness and, more generally, norms of interpersonal interaction has been increasingly recognized in the field of language teaching. In this field, too, the realization grew steadily over the last decade or so

that 'Grice's Razor,' which extolled the economical virtues of concentrating on the supposed universality of the underlying principles and which cut off unnecessary culture-specific explanations, spelled out a disaster for the students' communicative competence and their ability to survive socially in the milieu of their other language. As Kramsch (1993: 8–9) put it in her book *Context and culture in language teaching*, "If (...) language is seen as social practice, culture becomes the very core of language teaching. Cultural awareness must then be viewed both as enabling language proficiency and as being the outcome of reflection on language proficiency. (...) Once we recognize that language use is indissociable from the creation and transmission of culture, we have to deal with a variety of cultures."

The present writer's long polemics against the 'universals of politeness' and 'universal principles of human conversation' was rooted in her own experience as a language migrant (to use a term introduced by Besemeres, 2002) – from Polish into English, especially academic English, and also, into Australian English (Wierzbicka, 1997). On a very small scale, her 1997 cross-cultural memoir illustrates a noteworthy aspect of intercultural pragmatics as it has evolved over the last decade or so: the new alliance between, on the one hand, linguistic pragmatics, based on 'hard' linguistic evidence and rigorous linguistic analysis, and, on the other, the growing field of study focused on the 'soft' data of personal experience of cross-cultural and cross-linguistic living.

I will illustrate this alliance with three excerpts from that memoir, which deliberately takes a personal rather than objective perspective. As many recent writers on the subject have argued, such a personal perspective legitimizes the insistence with which proponents of intercultural pragmatics have been challenging, in the last decade or so, the earlier paradigms. Commenting on her life in Australia, to which she emigrated from Poland in 1972 (having married an Australian), the author wrote:

> I had to start learning new "cultural scripts" to live by, and in the process I became aware of the old "cultural scripts" which had governed my life hitherto. I also became aware, in the process, of the reality of "cultural scripts" and their importance to the way one lives one's life, to the image one projects, and even to one's personal identity.
>
> For example, when I was talking on the phone, from Australia, to my mother in Poland (15,000 km away), with my voice loud and excited, carrying much further than is customary in an Anglo conversation, my husband would signal to me: 'Don't shout!' For a long time, this perplexed and confused me: to me, this 'shouting' and this 'excitement' was an inherent part of my personality. Gradually, I came to realise that this very personality was in part culturally constituted. (Wierzbicka, 1997: 119)

The realization of the close links between one's ways of speaking, one's personality and one's cultural background raised for the author the question that countless other immigrants are constantly confronted with: to what extent was it desirable, or necessary, to adapt to one's new cultural context (changing oneself in the process)?

> Early in our life together, my husband objected to my too frequent – in his view – use of the expression *of course*. At first, this puzzled me, but eventually it dawned on me that using *of course* as broadly as its Polish counterpart *oczywiście* is normally used would imply that the interlocutor has overlooked something obvious. In the Polish 'confrontational' style of interaction such an implication is perfectly acceptable, and it is fully consistent with the use of such conversational particles such as, for example, *przecież* ('but obviously – can't you see?'). In mainstream Anglo culture, however, there is much more emphasis on 'tact', on avoiding direct clashes, and there are hardly any confrontational particles comparable with those mentioned above. *Of course* does exist, but even *of course* tends to be used more in agreement than in disagreement (e.g. 'Could you do X for me?' – 'Of course'). Years later, my bilingual daughter Mary told me that the Polish conversational expression *ależ oczywiście*: 'but-EMPHATIC of course' (which I would often replicate in English as 'but of course') struck her as especially 'foreign' from an Anglo cultural point of view; and my close friend and collaborator Cliff Goddard pointed out, tongue in cheek, that my most common way of addressing him (in English) was 'But Cliff....'. (Wierzbicka, 1997: 119)

Thus, the author had to learn to avoid overusing not only "of course" but also many other expressions dictated by her Polish cultural scripts; and in her working life at an Anglo university, this restraint proved invaluable, indeed essential.

> I had to learn to 'calm down', to become less 'sharp' and less 'blunt', less 'excitable', less 'extreme' in my judgements, more 'tactful' in their expression. I had to learn the use of Anglo understatement (instead of more hyperbolic and more emphatic Polish ways of speaking). I had to avoid sounding 'dogmatic', 'argumentative', 'emotional'. (There were lapses, of course.) Like the Polish-American writer Eva Hoffman (1989), I had to learn the use of English expressions such as 'on the one hand..., on the other hand', 'well yes', 'well no', or 'that's true, but on the other hand'.
>
> Thus, I was learning new ways of speaking, new patterns of communication, new modes of social interaction. I was learning the Anglo rules of turn-taking ('let me finish!', 'I haven't finished yet!'). I was learning not to use the imperative ('Do X!') in my daily interaction

> with people and to replace it with a broad range of interrogative devices ('Would you do X?' 'Could you do X?' 'Would you mind doing X?' 'How about doing X?' 'Why don't you do X?' 'Why not do X?', and so on). (Wierzbicka, 1997: 119–120)

As these quotes make clear, for writers whose view of intercultural pragmatics was informed by their own personal experience, their knowledge of what was involved was not purely theoretical: above all, it was practical. They were convinced that the insistence on cultural differences was not only theoretically justified (because these differences were real) but also that acknowledging them, and above all, describing them, was vitally important for the practical purposes of intercultural communication and understanding; and in the case of immigrants, of daily living.

The 1991 edition of Wierzbicka's *Cross-cultural pragmatics* was an attempt to challenge the Gricean and Brown and Levinsonian paradigms, and to expose the anglocentric character of various supposedly universal maxims, principles and concepts (including the key concept of 'face,' which was the linchpin of Brown and Levinson's theory of politeness). Twelve years later, when the expanded second edition of the book was published, the tide had changed. Nonetheless, paradoxically, while the universalist pragmatic frameworks developed in the 1970s were gradually losing their appeal, the program of actually **describing** the different ways of speaking and thinking linked with different cultures continued to encounter a great deal of resistance.

As the differences between cultures and subcultures were increasingly celebrated, there was also a growing suspicion of any generalizations as to what exactly these differences might be. Diversity was seen as beautiful but also as inherently elusive and indescribable. With the growing emphasis on diversity, the view gradually developed that diversity was everywhere, and that while those differences could and should be celebrated, they could not be described. Thus, in many quarters, there developed a great fear of the notion of culture (especially, a culture), and attempts to identify any differences between particular cultures came to be seen as static culturologies.

Those who promote intercultural pragmatics accept, of course, that cultures are not essences, that cultures are not monads, and that cultures have no fixed contours. But they refuse to conclude from this that cultures cannot be discussed, described, and compared at all. They point out that it would also be a conclusion denying the subjective experience of immigrants, and one going against their vital interests; and that to deny the validity of the notion of culture-specific discourse patterns (including Anglo discourse patterns) is to place the values of political correctness above the interests of socially disadvantaged individuals and groups. In particular, they argue that with the increasing domination of English in the world, both Anglos and non-Anglos need to learn about various Anglo cultural scripts, and that to try to describe these scripts, and to explain the values reflected in them, is not to indulge in stereotyping, but on the contrary, it is to help Anglos to overcome their inclination to stereotype immigrants as rude, while at the same time helping immigrants to better fit in, socially, and to improve their lives (cf., e.g., Wierzbicka, 2002a, 2002b).

In this context, it has become more and more clear that the key issue is that of the metalanguage in which different speech practices and norms can be usefully described and compared. At a time when the English language was commonly taken as a baseline for all comparisons, even those pragmaticists who were more interested in cross-linguistic variation than in supposed universals of politeness or a supposedly universal logic of conversation often assumed that English lexical categories provided legitimate analytical tools for such comparisons. In particular, it was widely assumed that English words such as 'request,' 'apology,' and 'compliment' could be relied on as such tools, and that one could study how requests, apologies, compliments and so on are realized in this or that language and culture (cf., e.g., Blum-Kulka *et al.*, 1989). The fact that many other languages do not have words corresponding in meaning to such English categories was either ignored or dismissed as unimportant.

Similarly, English folk-categories such as directness, formality, harmony or politeness were accepted uncritically as valid tools for intercultural pragmatics, as were also lexical categories of technical English such as 'face' (Brown and Levinson, 1978), 'relevance' (Sperber and Wilson, 1986) and so on. As discussed, for example, in Goddard (2004: 144), the ethnocentrism "inherent in choosing a descriptive metalanguage which is language-specific and culture-specific (. . .) necessarily imposes an 'outsider perspective'" on the language and culture described in such terms. At the same time, the alternative practice of using indigenous terms (e.g. *enryo*, *wa*, *omoiyari* in the case of Japanese) involved obvious translation problems in reverse.

The approach to intercultural pragmatics advocated and implemented in the so-called NSM approach seeks to solve the crucial problems of a suitable metalanguage for intercultural pragmatics by pointing to the existence of a shared lexical and grammatical core in all languages – a core which can be used as a culture-neutral and language-independent natural

semantic meta-language (hence the term "NSM"). This approach has now identified, on an empirical basis, 60 or so universal semantic primes, whose English exponents are linked with simple words such as 'good' and 'bad,' 'someone' and 'something,' 'people,' or 'know,' 'think,' and 'want.' (For exponents in languages other than English, see Goddard and Wierzbicka (eds.), 2002). Relying on this empirically established set of primes, the proponents of the NSM approach to intercultural pragmatics have produced a large body of detailed, highly specific descriptions of culture-specific norms and practices, formulated neither in technical or semitechnical English terms such as 'formal' and 'informal' or 'direct' and 'indirect,' nor in terms of English folk categories such as 'apology,' 'compliment,' 'sarcasm,' 'understatement' and so on, but rather, in terms of simple words which have equivalents in all languages.

The identification of universal semantic primes that have lexical exponents in all languages has allowed NSM researchers to develop a theory of cultural scripts, where a cultural script is a hypothesis about culture-specific attitudes, assumptions and norms formulated in simple words and testable in consultation with native speakers and cultural insiders. This theory has now produced a large body of fine-grained culture-specific descriptors and cross-cultural comparisons. (See, e.g., Goddard 1997, 2000, 2004; Goddard and Wierzbicka (eds.), 2004, in press; Wierzbicka, 1991/2003, 1996, 2002b.)

The proponents of the cultural scripts approach to intercultural pragmatics argue that the use of such concepts can free researchers from what Goddard (2004) calls "terminological ethnocentrism" and give them a neutral, culture-independent metalanguage for describing different cultural norms. At the same time, the use of such concepts allows them to capture the native speaker's point of view, without distorting it through the application of descriptive tools rooted in the English language or Anglo academic culture.

On this point, the NSM-based approach to cross-cultural pragmatics differs radically from that characteristic of works like Blum-Kulka *et al.*'s (1989) *Cross-cultural pragmatics: Requests and apologies* or Kasper (and the subsequent work by Blum-Kulka and her colleagues). The proponents of the NSM approach argue that while the works in this tradition must be appreciated for their attention to cultural differences reflected in ways of speaking, they cannot escape the charge of terminological, and not only terminological, ethnocentrism. Given that words such as 'requests' and 'apologies' stand for conceptual artifacts of the English language, using them as analytical tools inevitably involves imposing an Anglo perspective on other languages and cultures. To describe ways of speaking across languages and cultures in terms of folk categories encoded in English is like describing English talk in terms of Japanese, Hebrew or Russian folk categories (e.g., the Japanese *wakimae*, cf. Ide, 1989, the Hebrew *dugri*, cf. Katriel, 1986, or the Russian *vran'e*, cf. Wierzbicka, 2002b); but of course nobody would wish to describe English in such terms.

As the present author (cf., e.g., Wierzbicka, 1991/2003) and colleagues have repeatedly argued, the conviction shared by so many semanticists and pragmaticists that it is all right to try to describe all languages through English terms untranslatable into the language of speakers whose ways of thinking those terms are supposed to explain and illuminate, shows the same Anglocentrism that the Gricean and post-Gricean maxims, principles, and conversational postulates once did. Such an anglocentrism is sometimes defended in the name of science. For example, Kay and Berlin in various publications defend the use of English words such as 'color' to analyze thought processes of speakers of languages that have no word like 'color' in the name of scientific discourse. Their opponents (including the present author) argue that English has no special status in describing the ways of thinking of speakers of languages other than English. Words such as 'good' and 'bad' or 'say,' 'think,' 'know' and 'want,' which, as evidence suggests, have morpholexical exponents in all languages, free the analysts from an Anglo perspective, while allowing them at the same time to retain a mini-lexicon of 60 or so English words as a practical lingua franca for articulating different culture-specific conventions, norms and values (and more generally, ways of thinking). For example, claims that in many societies people are guided in their ways of speaking by principles such as 'don't impose' or 'be relevant' depend on the English words 'impose' and 'relevant,' which have no equivalents in other languages. To say that speakers of those other languages are deeply concerned about some values which – as it happens – can only be formulated in English means to give English a privileged position in the humankind's mental world.

The theory of cultural scripts seeks to formulate norms, values and principles of language use in words which, unlike 'impose' or 'relevant,' have equivalents in all other languages, that is words that, it is argued, stand for universal human concepts. These universal words (or word-like elements) are the same words in which semantically encoded meanings are also explicated.

For other current approaches to intercultural pragmatics, see, in particular, the first issue (2004, 1) of the new journal *Intercultural Pragmatics*.

Interjections

Interjections

Interjections are words that conventionally constitute utterances by themselves and express a speaker's current mental state or reaction toward an element in the linguistic or extralinguistic context (*see* **Context, Communicative**). Some English interjections are words such as *yuk*! 'I feel disgusted', *ow*! 'I feel sudden pain', *wow*! 'I feel surprised and I am impressed', *aha*! 'I now understand', *hey*! 'I want someone's attention', *damn*! 'I feel frustrated', and *bother*! 'I feel annoyed'. Such words are found in all languages of the world. This article surveys the different uses and definitions of the term 'interjection' and the different types of interjections that are found in the languages of the world. It also explores the relationship of interjections to other pragmatic devices such as particles, discourse markers, and speech formulae. (*see* **Formulaic Language**).

The Definition of Interjection

Interjections may be defined using formal, semantic, or pragmatic criteria. From a formal point of view, an interjection is typically defined as a lexical form that (a) conventionally constitutes a nonelliptical utterance by itself, (b) does not enter into construction with other word classes, (c) does not take inflectional or derivational affixes, and (d) is monomorphemic (*see* **Inflection and Derivation**).

This definition characterizes the core members of the interjection class. It captures most of the elements that have traditionally been described as interjections. In many languages this includes (a) words that are used to express emotions such as disgust and its related feelings, for example, English *yuk*!, *ugh*!, and *phew*!, German *pfui*!, Dakota *xox*!, Polish *fu*! and *fe*!, Russian *fu*!, and Danish *fy*!; (b) words and expressions for greetings, leave-taking, thanking, apologizing, etc. (English *hello*, *thank you*, and *goodbye*, French *adieu*); (c) swear words (English *shit*!, French *merde*! and *sacredieu*!); (d) attention-getting signals (English *hey* and *psst*, Russian *a'u*, Japanese *oi* and *nee*); (e) some particles and response words (English *yes* and *no*, Japanese *hai* and *iie*); (f) words directed at animals (English *whoa*); and (g) onomatopoeic words and iconic (*see* **Iconicity**) depictives (Polish *sza* 'hush' and *hu-hu* 'boo').

It, however, excludes some other items, such as English *well*, which have sometimes been included in the interjection class, because they are not capable of forming independent nonelliptical utterances. Some scholars believe that the formal definition, which is essentially the traditional definition, is too broad since it encompasses different semantically definable classes such as speech formulae that could be distinguished from the typical interjections on semantic grounds.
